FOURTH TRANSMITTAL OF AMENDED BRIEF ON APPEAL

Mail Stop APPEAL BRIEF-PATENTS
Commissioner for Patents
PO Box 1450
Alexandria, Virginia 22313-1450

Sir:

Transmitted herewith is an appeal brief in the above-identified application:

Submitted herewith in connection with the above application are the following:

- [X] Appellant's Fourth Amended Brief on Appeal.
- [X] Evidence Appendix (containing 10 references).

07/31/2007 CNGUYEN2 00000000 09190138

1590.00 OP

☒ Applicant hereby petitions for an extension of time under 37 C.F.R. §1.136(a) for the total number of months checked below:

<input checked="" type="checkbox"/> Extension for response filed within the fourth month:	\$1,590.00	<u>\$1,590.00</u>
EXTENSION FEE TOTAL:		<u>\$1,590.00</u>
Extension Fees Previously Paid:		<u>\$0.00</u>
TOTAL FEE:		<u>\$1,590.00</u>

A credit card payment form in the amount of \$1,590.00 is enclosed.

☐ Please charge Deposit Account No. 19-0741 in the amount of \$00.00. A duplicate copy of this transmittal is enclosed.

☒ The Commissioner is hereby authorized to charge any additional fees which may be required regarding this application under 37 C.F.R. §§ 1.16-1.17, or credit any overpayment, to Deposit Account No. 19-0741. Should no proper payment be enclosed herewith, as by a check being in the wrong amount, unsigned, post-dated, otherwise improper or informal or even entirely missing, the Commissioner is authorized to charge the unpaid amount to Deposit Account No. 19-0741. If any extensions of time are needed for timely acceptance of papers submitted herewith, applicant hereby petitions for such extension under 37 C.F.R. §1.136 and authorizes payment of any such extensions fees to Deposit Account No. 19-0741.

Please direct all correspondence to the undersigned attorney or agent at the address indicated below.

Respectfully submitted,

By

APPELLANT'S FOURTH AMENDED BRIEF ON APPEAL UNDER 37 C.F.R. § 41.37

Commissioner for Patents
P.O. Box 1450
Alexandria, VA 22313-1450

Sir:

Under the provisions of 37 C.F.R. § 41.37 and in response to the Notification of Non-Compliant Appeal Brief mailed on March 28, 2007 ("Notification"), Appellants submit this Fourth Amended Appeal Brief. To make this brief timely filed, Applicants also enclose a petition for an extension of four (4) months of time and the requisite fee as prescribed in 37 C.F.R. § 1.136.

The Notification stated that Appellants' previously amended appeal brief, filed on October 6, 2006, was non-compliant because each ground for rejection was not treated under a separate heading noting relevant claim numbers. The present brief conforms to the required format.

Appellants authorize the Commissioner to charge any deficiency (or credit any balance) to the undersigned deposit account 19-0741 if any fees are due.

I. REAL PARTY IN INTEREST

The real party in interest is ELAN PHARMA INTERNATIONAL, LTD. The inventors assigned their right, title, and interest in this application to NANOSYSTEMS LLC on January 6 and 11, 1999. This assignment was recorded in the U.S. Patent and Trademark Office at Reel 009861, Frame 0227. NANOSYSTEMS LLC subsequently assigned its right, title, and interest in this application to ELAN PHARMA INTERNATIONAL, LTD. This assignment was recorded in the U.S. Patent and Trademark Office at Reel 011079, Frame 0301.

II. RELATED APPEALS AND INTERFERENCES

Appellants are not aware of any appeals or interferences related to the present application.

III. STATUS OF CLAIMS

Pending claims: 11-36, 40-45, 47-49, and 51-121.

Rejected claims: 11-36, 40-45, 47-49, and 51-121.

Appealed claims: 11-36, 40-45, 47-49, and 51-121.

IV. STATUS OF AMENDMENTS

An after-final response, filed on May 14, 2004, sought to amend independent claims 11, 23, 35, 40, and 42-44. In light of the Advisory Action dated July 22, 2004, and according to the Examiner's Answer entered on May 26, 2006, Appellants understand that the amendments have been entered for purposes of the present appeal. Consequently, the appended claims and their status identifiers reflect the entry of the amendments.

V. SUMMARY OF CLAIMED SUBJECT MATTER

The claimed invention is directed to dry powder aerosol compositions of nanoparticulate crystalline drugs for pulmonary and nasal delivery and to methods of making and using the compositions.¹ The claimed compositions comprise spherically-shaped aggregates of crystalline drug nanoparticles having a surface modifier adsorbed to the surface thereof.² The drug particles must be crystalline³ and exhibit an effective average particle size of less than about 1 micron.⁴ The diameters of the spherically-shaped aggregates are equal to or less than about 100 microns.⁵ Finally, the aggregates yield a nanoparticulate drug dispersion upon reconstitution in an aqueous medium.⁶

Having generally identified textual support for the claimed invention, Appellants present the following chart that identifies passages of the specification which describe the subject matter as claimed in each independent claim.⁷

Independent Claim	Claimed Subject Matter	Support in the Specification
11	dry powder aerosol compositions, formed from spray-drying, of nanoparticulate crystalline drugs for pulmonary and nasal delivery	page 7, lines 24-25; page 8, line 9 to page 9, line 2; and page 16, lines 11-12
	spherically-shaped aggregates of crystalline drug nanoparticles having a surface modifier adsorbed to the surface thereof	page 17, lines 6-7; page 20, lines 23; and page 33, line 16
	aggregates are less than or equal to about 100 microns in diameter	page 4, lines 11-12; page 13, lines 27-28; and page 21, line 4
	drug particles must be crystalline	page 24, lines 26-28

44	Method of making dry powder nanoparticulate drug composition comprising forming an aqueous nanoparticulate dispersions of poorly soluble drug	Page 18, lines 19-25
	dispersion comprises a poorly soluble drug	Page 8, line 10-12

Independent Claim	Claimed Subject Matter	Support in the Specification
	Drug solubility in at least one liquid dispersion medium is less than about 10 mg/mL	Page 25, lines 1-3
	Drug is crystalline	Page 24, lines 24-27
	nanoparticles have a surface modifier adsorbed to the surface thereof	page 17, lines 6-7; page 20, lines 23; and page 33, line 16
	effective average particle size of less than about 1 micron	page 7, lines 5-6 and page 13, lines 2-8
	Freeze-drying the nanoparticulate dispersion to form a dry powder of spherically shaped aggregates	Page 22, lines 11-19
	aggregates are less than or equal to about 100 microns in diameter	page 4, lines 11-12; page 13, lines 27-28; and page 21, line 4
	aggregates must yield back the nanoparticulate drug dispersions upon reconstitution in an aqueous medium	page 8, line 28; page 9, line 17; page 33, lines 19-22; and page 34, lines 28-30

Appellants' discovery is a substantial advance over conventional micronized drug formulations that are intended for delivery to the pulmonary and nasal regions. The nanoparticulate drug particle size facilitates the drug particles' fitting into a wide aggregate size range. Consequently, aggregate particles measuring less than about 2 microns up to about 100 microns uniformly contain the same concentration of nanoparticulate drug particles, by contrast to conventional micronized formulations, and thereby allow more effective and efficient drug delivery to a desired region.⁸ Moreover, the claimed invention results in more favorable drug delivery profiles relative to micronized drugs on account of the nanoparticulate drug size allowing more concentrated unit doses.⁹ Additionally, a number of advantageous bulk properties result from the claimed compositions. For example, the claimed compositions can be nebulized ultrasonically whereas

⁸ See specification at page 23, line 26 to page 24, line 6.

⁹ *Id.* at page 23, lines 17-22.

micronized drug dispersions cannot.¹⁰ By contrast to micronized drugs, the claimed invention also enables very rapid drug delivery to pulmonary and nasal surfaces.¹¹

¹⁰ *Id.* at page 23, lines 23-25.

¹¹ *Id.* at page 24, lines 7-10 and 15-18.

VI. GROUNDS OF REJECTION TO BE REVIEWED ON APPEAL

Four grounds for rejection remain after the issuance of the Final Office Action dated January 14, 2004:

- A. Whether claims 11-34, 40, 41, 44, 45, 47, 48, 51-62, 69-96, and 111-119 are unpatentable under 35 U.S.C. § 103(a) over U.S. Pat. No. 5,985,309 to Edwards *et al.* (“Edwards”).**
- B. Whether claims 11-34, 40- 45, 47, 48, 51-62, 65-96, and 97-119 are unpatentable under 35 U.S.C. § 103(a) over Edwards in view of U.S. Pat. No. 5,145,684 *et al.* to Liversidge (“Liversidge”).**
- C. Whether claims 35, 36, 49, 63, and 64 are unpatentable under 35 U.S.C. § 103(a) over Edwards in view of U.S. Pat. No. 5,202,110 to Dalby *et al.* (“Dalby”).**
- D. Whether claims 120 and 121 are unpatentable under 35 U.S.C. § 103(a) over Edwards in view of Goodman & Gilman’s, *The Pharmacological Basis of Therapeutics*, Ninth edition, page 666 (McGraw-Hill, 1996) (“Goodman”).**

VII. ARGUMENT

The claimed invention is patentable because none of the cited prior art references supports any of the PTO's stated grounds for rejection. The PTO has the initial burden of showing that the cited references establish a *prima facie* case of obviousness.¹² In doing so, the PTO's grounds for rejection must satisfy three basic criteria. First, "all the claim limitations must be taught or suggested by the prior art."¹³

Second, there must be some suggestion or motivation, either in the references themselves or in the knowledge generally available to one of ordinary skill in the art, to modify the reference or to combine reference teachings.¹⁴ "While the [U.S. Supreme] Court recently rejected a rigid application of the teaching, suggestion, or motivation ("TSM") test in an obviousness inquiry, the Court acknowledged the importance of identifying 'a reason that would have prompted a person of ordinary skill in the relevant field to combine the elements in the way the claimed new invention does' in an obviousness determination."¹⁵

Finally, there must be evidence of a reasonable expectation that the suggested modifications to or combination of the prior art references will be successful.¹⁶ The *KSR* Court explained that where a person of ordinary skill in the art has "good reason to pursue the known options within his or her technical grasp," and such pursuit "leads to the anticipated success, it is likely the product not of innovation but of ordinary skill and common sense."¹⁷

¹² See *In re Rinehart*, 531 F.2d 1048, 189 USPQ 143 (CCPA 1976).

¹³ *In re Royka*, 490 F.2d 981, 180 USPQ 580 (CCPA 1974).

¹⁴ See *In re Kahn*, 441 F.3d 977, 78 USPQ2d 1329 (Fed. Cir. 2006).

¹⁵ *Takeda Chemical Industries, Ltd. v. Alphapharm Pty., Ltd.*, --- F.3d---, 2007 WL 1839698 (Fed. Cir. 2007) (citing *KSR Intl. Co. v. Teleflex Inc.* 127 S.Ct. 1727, 1741, 82 USPQ2d 1385, 1396 (2007)).

¹⁶ See *In re Merck & Co., Inc.*, 800 F.2d 1091, 213 USPQ 375 (Fed. Cir. 1986).

¹⁷ *KSR Intl. Co. v. Teleflex Inc.* 127 S.Ct. 1727, 1742, 82 USPQ2d 1385, 1398 (2007).

Specifically, *none* of the cited references, alone or in combination with each other, teach or suggest the following elements that are required by each of Appellants' claims: (1) spherically-shaped aggregates of drug nanoparticles having a surface modifier adsorbed to the surface thereof, (2) crystalline drug nanoparticles, (3) drug nanoparticles having an effective average particle size of less than about 1 micron, and (4) the spherically-shaped aggregates produce nanoparticulate drug dispersions upon reconstitution in an aqueous medium. Furthermore, the PTO has not properly established a motivation to modify Edwards alone or by any of the cited secondary references to obtain the claimed invention.

A. Rejection of Claims 11-34, 40, 41, 44, 45, 47, 48, 51-62, 69-96, and 111-119 Under 35 U.S.C. § 103(a) over U.S. Pat. No. 5,985,309 to Edwards *et al.* ("Edwards")

Edwards fails to teach or suggest each limitation of the claimed invention, and a person of ordinary skill in the art would not have been motivated to modify the reference in a manner so as to arrive at the claimed invention.

1. The PTO Applied an Improper Standard in Determining Whether Edwards Teaches or Suggests a *Nanoparticulate Drug*

Because Edwards teaches only *microparticulate* drug compositions, the reference utterly fails to suggest the claimed *nanoparticulate* drug composition. Specifically, Edwards discloses particles having a mean diameter of between approximately 5 μm and 30 μm and comprising a therapeutic agent and a surfactant for administration to the respiratory tract *via* an aerosol formulation.¹⁸ Additionally, Edwards discloses a number of processes for making particles that conform to these size requirements.¹⁹ Consequently, none of the prior art particles nor the processes for making them remotely suggests that the particles comprise *nanoparticulate* drug.

¹⁸ See Edwards at col. 3, lines 1-3; col. 5, lines 29-33; and col. 6, lines 1-7.

¹⁹ See, *id.* at col. 8., lines 5-29.

a. Edwards Does Not Teach or Suggest Drug Nanoparticles

Not once during the pendency of this application has the PTO articulated how a person of ordinary skill would understand Edwards to teach or suggest drug nanoparticles, much less those that form spherically-shaped aggregates as required by Appellants' claims. In fact, the PTO recognized that "Edwards *et al.* do not specifically state that 50% of the [disclosed] particles have a geometric particle size of less than about 1 μm [as claimed]."²⁰ Nonetheless, the "examiner's position [is] that Edwards disclosed that nanosize drug particles in aerosol form were delivered to the alveoli of the lung."²¹

Edwards simply teaches nothing of the sort.²² Edwards teaches that "[a]dministration by aerolization permits deep lung delivery of *relatively large diameter* therapeutic aerosols, for example, greater than 5 μm in mean diameter."²³ In doing so, Edwards flatly refutes the PTO's contention that the reference teaches nanoparticulate drug on account of drug particles reaching the deep lung.

Moreover, the PTO invoked an incorrect legal standard by persistently requiring Appellants to first establish the recited nanoparticulate drug size as a critical feature of the invention before patentability over Edwards would be acknowledged. It is black letter law that "[t]he examiner bears the burden of establishing a *prima facie* case of obviousness."²⁴ "Only if this burden is met does the burden of coming forward with rebuttal argument or evidence shift to the applicant."²⁵ In this analysis, "[a]ll words in a claim must be considered in judging the patentability of that claim against the prior art."²⁶ In particular, "[o]bviousness requires a suggestion of all elements in a claim."²⁷ The

²⁰ Office Action dated February 5, 2001 at page 5.

²¹ Final Office Action dated February 14, 2004 at page 5.

²² See Appellants' Response, dated May 14, 2004, at pages 23-24.

²³ Edwards at col. 5, lines 31-34 (emphasis supplied).

²⁴ *In re Deuel*, 51 F. 3d 1552, 1557 (Fed. Cir. 1995) (citing *In re Rijckaert*, 9 F. 3d 1531, 1532 (Fed. Cir. 1993); *In re Oetiker*, 977 F. 2d 1443, 1445 (Fed. Cir. 1992)).

²⁵ *Rijckaert*, 9 F. 3d at 1532 (emphasis supplied).

²⁶ *In re Wilson*, 424 F. 2d 1382, 1385 (CCPA 1970).

PTO therefore is obligated to consider that Appellants' claimed composition comprises nanoparticulate drug particles and to bear the initial burden of determining whether Edwards teaches or suggests this feature of Appellants' claimed invention.

By contrast to the principles stated above, the PTO improperly "granted [no] patentable weight" to the "merely superfluous" nanoparticulate size limitation,²⁸ and consequently the PTO adopted without explanation the notion that "the compositions of the instant claims and those of [Edwards] do not appear to be different."²⁹ In this context, the PTO has now maintained the present rejection because Appellants "did not present factual evidence showing criticality of size of the nanoparticles of drug in the instant claims that is different than the size of particles of drug in the [cited prior art]; *specifically Edwards*."³⁰

b. The PTO Failed to Justify its Conclusion of Obviousness Based on the Difference in Particle Sizes

In the Examiner's Answer,³¹ contrary to the explicit teaching of Edward, the Examiner alleged that Edwards teaches nanosized drug particles:

... both the polymers comprising the micron-sized particles taught by Edwards and the therapeutic agents contained therein are *obviously* nanosized particles, because the size of the molecules are on the nanometer length scale.³²

Furthermore, given that the particles taught by Edwards are micron-sized, these are *obviously* aggregates of nanometer particles (i.e., molecules), because it is only through the association (i.e.,

²⁷ *In re Royka*, 490 F. 2d 981 (CCPA 1974).

²⁸ See Office Action dated August 21, 2000 at page 5,

²⁹ Office Action dated August 27, 2001 at page 5.

³⁰ Advisory Action dated July 22, 2004 at page 2 (emphasis supplied).

³¹ Prior to receiving the Notification of Non-Compliant Appeal Brief, the PTO issued, and Appellants received, an Examiner's Answer in reply to Appellant's previous amended appeal brief filed on October 6, 2006. In the interest of economy, therefore, Appellants take this opportunity to also address the Examiner's Answer.

³² Examiner's Answer at 11-12 bridging (emphasis added).

aggregation) of nanometer-sized molecules via intermolecular interactions that micron-sized particles could result.³³

The PTO has not just embellished Edwards' disclosure to admit of nanoparticulate drug particles: it unabashedly *pronounced as obvious* Appellants' recited nanoparticle size based upon not even a scintilla of evidence, sound scientific reasoning, any passage in Edwards, and certainly not upon any appeal to "the inferences and creative steps that a person of ordinary skill in the art would employ."³⁴ "[T]he examiner must present a convincing line of reasoning as to why the artisan would have found the claimed invention to have been obvious in light of the teachings of the references."³⁵

The PTO's analysis further hinges upon its twice-asserted notion that because molecules are "on the nanometer length scale," so, too, are the sizes of particles comprising those molecules. Drug molecule size bears upon absolutely no measure of drug particle size. What is relevant, as Appellants have repeatedly stressed, is whether Edwards teaches or suggests Appellants' claimed dry powder aerosol and its methods of manufacture and use. Nowhere does Edwards hint that its microparticles are aggregates of nanoparticles or even "association[s] of . . . nanometer-sized molecules."³⁶

**c. Edwards Teaches Away From Appellants' Aggregates
Comprising Nanoparticulate Drug Particles**

Evidence that Appellants' claimed invention is not obvious is the fact that Edwards teaches away from Appellants' claimed invention because the reference strongly suggests that nanoparticles

³³ *Id.* at 12 (emphasis added).

³⁴ *KSR* 127 S.Ct. at 1742, 82 USPQ2d at 1397.

³⁵ *Ex parte Clapp* 227 USPQ 972, 973 (Bd. Pat. App. & Interf. 1985). *See also Ex parte Levensgood* 28 USPQ2d 1300 (Bd. Pat. App. & Interf. 1993). The PTO's own instructions to patent examiners describes various potential sources of rationales to modify or combine references, but the PTO here has not availed itself of even one of those sources. *See* MPEP § 2144 (Rev. 5, Aug. 2006).

³⁶ Examiner's Answer at 12.

would be ineffective for delivery of a drug to the pulmonary system. “[R]eferences that teach away cannot serve to create a prima facie case of obviousness.”³⁷

Here, Edwards teaches that larger drug particles, *e.g.*, those having a mean diameter between 5 μm and 30 μm , are used to provide maximum deposition of the drug within the lungs.³⁸ Moreover, the larger particles of Edwards avoid the fate of “very small particles of less than five microns in diameter, preferably between one and three microns in diameter, which are then subject to phagocytosis.”³⁹ Edwards therefore teaches that inhalation of larger, not smaller, drug particles are necessary for delivery of the drug to the lungs to avoid the risk of phagocytosis. Consequently, a person of ordinary skill in the art would have been dissuaded by Edwards from making smaller drug particles for their delivery to the lung.

2. Edwards Teaches *Amorphous* Drug Particles, Whereas the Claims Require *Crystalline* Drug Nanoparticles

Moreover, Edwards does not teach or suggest that the drug must be crystalline, as required by each of Appellants’ claims. Edwards teaches several methods of manufacturing the disclosed drug microparticles, including emulsion solvent evaporation and spray drying, that result in *amorphous* drug substances.⁴⁰

In contrast to the amorphous particles of Edwards, Appellants’ claimed invention requires crystalline drug nanoparticles. In light of this difference, the PTO has failed to articulate why a person of ordinary skill in the art would have sought to modify the compositions of Edwards to arrive at dry powder aggregates comprising nanoparticulate *crystalline* drug.

³⁷ *McGinley v. Franklin Sports, Inc.*, 262 F. 3d 1339, 1354 (Fed. Cir. 2001) (citing *In re Gurley*, 27 F. 3d 551, 553 (Fed. Cir. 1994)).

³⁸ See Edwards at col. 5, lines 10-15.

³⁹ *Id.* at col. 5, lines 16-18.

⁴⁰ See Appellants’ Response dated July 11, 2002 at page 6. See also Edwards at col. 8, lines 7-10; col. 13, lines 49 to col. 14, line 19 (Example 1; evaporation); col. 14, lines 21 to 49 (Example 2; spray-drying).

Evidently recognizing that Edwards fails on this score, the PTO again invoked its novel theory of obviousness:

The selection of a crystalline therapeutic agent is *obviously* something that would have been apparent to a person of ordinary skill in the art, especially given that “recrystallization” is a commonly used purification technique of small molecule therapeutics.⁴¹

No scientific reasoning, guiding methodology, or even reference to legal precedent is proffered to explain why this purported fact is so obvious or apparent. Moreover, even if one were to accept this “obvious” notion, the PTO’s argument completely misses the mark: the claims require the recited composition to comprise a crystalline drug, and so it is entirely irrelevant what morphology of a drug may result from purification by recrystallization, or what morphology might be selected in a starting material. What is relevant is the absence of any apparent reason for the skilled artisan to select a crystalline drug for inhalable drug formulations where Edwards expressly suggests the use of *amorphous* drug particles.

3. Edwards Does not Teach or Suggest Spherically Shaped Aggregates

Appellants’ claimed invention is further patentable over Edwards because Appellants’ claims require spherically-shaped aggregates, whereas Edwards, in contrast, teaches microparticles that are “rough (non-smooth) [and] non-spherical . . .”⁴²

Moreover, Edwards teaches away from Appellants’ claimed invention because the reference emphasizes that the aerodynamic lightness of the disclosed particles is achieved in part by creating irregular surface structures on the particles.⁴³

In the Examiner’s Answer, the PTO lifts from Edwards a single passage to fortify its position:

⁴¹ Examiner’s Answer at 13.

⁴² Edwards at col. 9, lines 15-17.

The polymeric particles are preferably prepared by spray drying. Prior methods of spray drying, such as that disclosed in PCT WO 96/09814 by Sutton and Johnson, disclose the preparation of smooth, spherical microparticles of a water-soluble material with at least 90% of the particles possessing a mean size between 1 and 10 μm . *The method disclosed herein provides rough (non-smooth), non-spherical microparticles that include a water-soluble material combined with a water-insoluble material.* At least 90% of the particles possess a mean size between 5 and 30 μm , and a low mass or tap density (less than 0.4 g/cc).⁴⁴

Thus, Edwards distinguishes its method and particles from the prior art evidently represented by WO 96/09814 by explicitly stating that Edwards' method yields non-spherical microparticles.⁴⁵ Taking the view that Edwards discloses exactly the opposite, *i.e.*, spherical particles, has no factual or legal basis.⁴⁶ Edwards, therefore, flatly contradicts the PTO's position: the reference does not teach or suggest the recited spherically shaped aggregates. Because Edwards achieves its stated objective by utilizing non-spherical particles, there is no apparent reason why a person of ordinary skill in the art would select spherically shaped aggregates.

4. Because Edwards Teaches Large Particles That "Degrade," Edwards Fails to Teach or Suggest the Claimed Aggregates That Yield Nanoparticulate Drug Dispersions

The PTO has not rebutted Appellants' arguments that Edwards does not teach or suggest that the claimed aggregates of nanoparticulate drug return to nanoparticulate drug particle dispersions upon reconstitution in an aqueous liquid medium.⁴⁷ "Obviousness requires a suggestion of all

⁴³ See *id.* at col. 5, lines 64-67.

⁴⁴ Edwards at col. 9, lines 11-21 (emphasis added).

⁴⁵ The PTO does not cite and apparently does not even rely upon WO 96/09814, which in any event, according to Edwards, concerns particles of a *water-soluble* material where at least 90% of the particles have a mean size between 1 and 10 μm , in stark contrast to the requirements of Appellants' claims (*i.e.*, poorly soluble drug and effective average particle size of less than about 1000 nm).

⁴⁶ The PTO's mischaracterization of Edwards in this regard is not an oversight. Throughout prosecution, the PTO repeatedly has relied upon this single passage. See, *e.g.*, Examiner's Answer at 11 and Office Action dated January 14, 2004 at 2.

⁴⁷ See Appellants' Response dated May 14, 2004 at page 25.

elements in a claim.”⁴⁸ The PTO is thus required to articulate why this feature of Appellants’ invention would have been obvious.

The PTO characterized the reference as teaching the variance of a number of parameters that would facilitate the prior art particles in reaching selected regions of the respiratory tract.⁴⁹ This is irrelevant: the reference still does not teach or suggest that aggregates as claimed are reconstituted into nanoparticulate drug particle dispersions. In fact, Edwards teaches instead that the disclosed large and aerodynamically light drug particles simply “undergo slow degradation and drug release.”⁵⁰ There is no evidence whatsoever that what results from such degradation and slow release is a nanoparticulate particle dispersion.

Regarding this issue, the Examiner’s Answer presents essentially three arguments that bear no relation to this feature of the claimed invention.

First, the PTO argued that “Appellant claims nanoparticles of drug and not a liquid dispersion medium.”⁵¹ This statement is absolutely false: Appellants never asserted to claim drug nanoparticles. What Appellants do claim are *dry powder aerosols* comprising the recited aggregates that return to nanoparticulate drug dispersions upon reconstitution in an aqueous liquid medium.⁵²

Second, the PTO “note[s] that Appellant indicates no specific liquid medium for dispersion of the drug particles.”⁵³ The statement is false: the claims explicitly define “an aqueous liquid medium.”⁵⁴

⁴⁸ *In re Royka*, 490 F. 2d 981 (CCPA 1974).

⁴⁹ See Office Action dated January 14, 2004 at page 3 (citing Edwards at col. 10, lines 45-55).

⁵⁰ Edwards at col. 10, lines 37-38.

⁵¹ Examiner’s Answer at 12.

⁵² See, e.g. claim 1(c).

⁵³ Examiner’s Answer at 12.

⁵⁴ See, e.g. claim 1(c).

Finally, the PTO attempted to rebut Appellants' earlier arguments by summarizing certain passages in Edwards that are relevant to nothing about the claimed invention. Thus, for instance, the PTO relied upon Edwards' teaching that "drug particles may be fabricated with appropriate material, surface roughness, diameter and tap density for localized delivery to selected regions of the respiratory tract including delivery to the alveoli."⁵⁵ While this might be a fair synopsis of Edwards, it does not address the fact that Edwards does not teach or suggest any of the features of Appellants' claimed invention.

5. Conclusion

For all of these reasons, Edwards fails to support the PTO's rejection, and so the claimed invention is patentable over Edwards. Consequently, the Board should reconsider and reverse the rejection.

B. Rejection of Claims 11-34, 40- 45, 47, 48, 51-62, 65-96, and 97-119 Under 35 U.S.C. § 103(a) Over Edwards in View of U.S. Pat. No. 5,145,684 to Liversidge *et al.* ("Liversidge")

Edwards in combination with Liversidge does not obviate the claimed invention because Liversidge remedies none of the deficiencies of Edwards discussed above and because the references militate against making the claimed compositions. Specifically, Liversidge is directed to a composition of a "crystalline drug substance having a surface modifier adsorbed on the surface thereof . . . to maintain an effective average particle size of less than about 400 nm."⁵⁶ The nanoparticulate compositions of Liversidge are disclosed as being useful in oral, parenteral, and intravenous administration applications.⁵⁷

⁵⁵ Examiner's Answer at 12 (internal citations omitted).

⁵⁶ Liversidge at col. 2, lines 38-43. T

⁵⁷ *See id.* at col. 8, lines 10-13.

In contrast, Edwards discloses “aerodynamically light particles generally hav[ing] a mean diameter between 5 μm and 30 μm ”⁵⁸ for “delivery of a therapeutic agent to the airways of the alveolar region of the lung.”⁵⁹ The references thus embody: (1) non-obvious variants of drug compositions and (2) non-overlapping routes of administration. Neither reference therefore suggests the claimed aggregate of nanoparticulate drug dispersions nor does the PTO demonstrate how one of ordinary skill in the art would modify the light particles of Edwards with the comparatively dense crystalline particles of Liversidge to arrive at the claimed invention.

Moreover, Edwards teaches away from the proposed combination of prior art references because Edwards discloses that small drug particles are not useful in the context of pulmonary drug delivery. “If references taken in combination would produce a ‘seemingly inoperative device,’ . . . such references teach away from the combination and thus cannot serve as predicates for a prima facie case of obviousness.”⁶⁰ As set forth above, Edwards is directed to large drug particles, *i.e.*, 5 μm to 30 μm , to avoid the fate of “very small particles of less than five microns in diameter, preferably between one and three microns in diameter, which are then subject to phagocytosis.”⁶¹ Therefore, a person of ordinary skill in the art would have been dissuaded by Edwards from using the nanoparticulate compositions of Liversidge in a modification of Edwards to arrive at the claimed dry powder aerosol.

In response to Appellants’ arguments, The PTO propounded two theories. First, the PTO pronounced that “the disclosures in Leversidge [*sic*, “Liversidge”] . . . are in the same field of endeavor as that in Edwards – nanosize drug particles that are surface modified in liquid

⁵⁸ Edwards at col. 4, lines 1-4,

⁵⁹ *Id.* at col. 4, lines 19-20.

⁶⁰ See *McGinley v. Franklin Sports, Inc.*, 262 F. 3d 1339, 1354 (Fed. Cir. 2001) (quoting *In re Spinnoble*, 405 F. 2d 578, 587 (CCPA 1969)).

⁶¹ Edwards at col. 5, lines 16-18.

dispersion.”⁶² But Edwards and Liversidge are *not* both directed to nanoparticulate drug particles.⁶³ Specifically, as discussed above, Edwards does not teach or suggest drug nanoparticles.

Second, the PTO styled Liversidge as “address[ing] similar problems that were raised in Edwards concerning nanosize drug delivery formulations through the respiratory tract . . .” Even a cursory inspection of Liversidge indicates that this is not so: Liversidge teaches “that the pharmaceutical compositions of this invention will be particularly useful in oral and parenteral, including intravenous, administration applications.”⁶⁴ Liversidge simply does not teach the administration of “nanosize drug delivery formulations through the respiratory tract.”⁶⁵

Furthermore, the Examiner’s Answer presents an illogical argument as to how Liversidge encompasses pulmonary delivery of drugs:

Oral administration encompasses oral inhalation, and therefore administration to the respiratory system.

Delivery through the mouth is termed “oral” and delivery via the nose is termed “nasal.”⁶⁶

Such ‘logic’ cannot survive even a gentle application of common sense. The skilled artisan imbued with knowledge of the pharmaceutical arts clearly would understand that “oral administration” targets the oral cavity and/or gastrointestinal tract, while “oral inhalation” targets the pulmonary tract. To drive the point home, one does not inhale a pill, nor does one swallow an aerosol.

⁶² Office Action dated January 14, 2004 at page 4.

⁶³ See Appellants’ Response dated May 14, 2004 at page 27.

⁶⁴ Liversidge at col. 8, lines 10-13.

⁶⁵ Office Action dated January 14, 2004 at page 4.

⁶⁶ Examiner’s Answer at 14.

Because the PTO has not advanced any credible reason why Edward and Liversidge can be properly combined in a manner so as to render obvious the invention, the claims are patentable over this combination of references, and so the Board should reverse this ground for rejection.

C. Rejection of Claims 35, 36, 49, 63, and 64 Under 35 U.S.C. § 103(a) over Edwards in View of U.S. Pat. No. 5,202,110 to Dalby (“Dalby”)

The combination of Edwards and Dalby does not obviate the claimed invention because Edwards is not a competent reference and because Dalby fails to remedy the deficiencies of Edwards. The PTO relies upon Edwards here “for all that it teaches as stated previously”⁶⁷ and, in particular, for the reference’s alleged disclosure of “spherical, nanosize aerosol particles of drug . . .”⁶⁸ Additionally, the PTO cites Dalby “for teaching propellant metered dose inhalers where the propellant is a ‘non-CFC’ propellant.”⁶⁹

For all of the foregoing reasons, Edwards does not teach or suggest the claimed invention. Specifically, nowhere does Edwards disclose the cited “spherical, nanosize aerosol particles of drug . . .” In contrast to the PTO’s characterization of the reference, Edwards teaches aerosol particles that have “a mean diameter of between approximately 5 μm and 30 μm ”⁷⁰ that are rough (non-smooth) [and] non-spherical . . .”⁷¹

Dalby, as with Edwards, does not teach or suggest aggregates of crystalline, nanoparticulate drug particles as required by each of Appellants’ claims. Dalby is directed to formulations of beclomethasone dipropionate for aerosol delivery *via* a metered dose inhaler.⁷² In particular, Dalby teaches that “the micronized drug . . . should be easily dispersible in the propellant or propellant

⁶⁷ Office Action dated December 24, 2004 at page 4,

⁶⁸ Office Action dated January 14, 2004 at page 4.

⁶⁹ See Office Action dated December 24, 2004 at page 4. See also Office Action dated January 14, 2004 at page 4.

⁷⁰ Edwards at col. 6, lines 1-7,

⁷¹ *Id.* at col. 9, lines 15-17.

blend with the aid of a surfactant, or completely dissolve.”⁷³ Dalby therefore does not teach or suggest that the disclosed drug particles are or should be crystalline, much less that the particles form spherically-shaped aggregates measuring less than or equal to about 100 microns in diameter as claimed.

In the PTO’s own words: “Dalby was relied on as teaching the propellant or aerosolized formulation for delivery of nanosized beclomethasone particles . . .”⁷⁴ But Dalby does not teach nanosized beclomethasone. At best, Dalby generally admits of drug particle sizes falling within the exemplary range of 0.1 to 10 μm ,⁷⁵ which is not the same as or suggestive of the claimed effective average size of less than about 1000 nm.

Thus, if the skilled artisan were to combine Edwards and Dalby, the claimed nanoparticulate drug composition would not result. Moreover, as discussed above, Edwards explicitly counsels against smaller particle sizes, preferring instead those with a mean diameter of about 5 to 30 μm . Edwards and Dalby, therefore, fail to support this ground for rejection, and so Appellants urge the Board to reverse it.

D. Rejection of Claims 120 and 121 Under 35 U.S.C. § 103(a) over Edwards in View of Goodman & Gilman’s, *The Pharmacological Basis of Therapeutics*, Ninth edition, page 666 (McGraw-Hill, 1996) (“Goodman”)

The combination of Edwards and Goodman fails to support the PTO’s obviousness rejection because Goodman does not remedy the deficiencies of Edwards discussed above. The PTO relied upon Goodman simply to the extent that the reference “teaches . . . beclomethasone dipropionate . . . [as a] steroid administered for asthma in aerosol formulations.”⁷⁶

⁷² See Dalby at col. 2, lines 22-26.

⁷³ *Id.* at col. 2, lines 36-38.

⁷⁴ Examiner’s Answer at 14.

⁷⁵ See Dalby at col. 2, line 45.

⁷⁶ Office Action dated December 24, 2002 at page 6.

Goodman does not address the requisite: (1) spherically-shaped aggregates of drug nanoparticles having a surface modifier adsorbed to the surface thereof, (2) drug nanoparticles that are crystalline and (3) that have an effective average particle size of less than about 1 micron, and (4) spherically-shaped aggregates that must yield back nanoparticulate drug dispersions upon reconstitution in an aqueous medium. Because Edwards also does not teach or suggest any of these claimed features of Appellants' invention, *supra*, the combination of Edwards and Goodman also fails to do so.

The PTO asserted that Goodman, *via* its disclosure of beclomethasone dipropionate being available in aerosol formulations and therefore useful for treating asthma, suggests the use of the drug in the formulations of Edwards.⁷⁷ Goodman adds nothing material to Edwards that would undermine the patentability of the claims. For the reasons given above, Edwards is not a competent reference, and so the PTO's reliance upon Goodman here is wholly unavailing. Accordingly, the Board should also reverse this ground for rejection.

⁷⁷ Office Action dated December 24, 2002 at page 6.

E. Conclusion

Edwards, alone or in combination with any of the cited secondary references, does not teach or suggest the claimed dry powder aerosol comprising spherically-shaped aggregates of crystalline, submicron-sized drug nanoparticles. Further evidence of non-obviousness is the fact that Edwards specifically teaches away from the use of heavier smaller drug particles and teaches away from the use of spherically-shaped particles. Because none of the secondary references would persuade the skilled artisan to discount or ignore the express teaching of Edwards, or at least suggest that the compositions of Edwards be modified so as to yield the claimed invention, the PTO has failed to establish that Edwards and the cited combinations of prior art references render the claims obvious. For all of these reasons, Appellants courteously request the Board to reconsider and reverse all grounds for rejection of the claims.

VIII. CLAIMS APPENDIX

1. – 10. (cancelled).

11. (Previously presented) A dry powder aerosol composition for pulmonary or nasal delivery comprising spherically shaped aggregates formed from spray-drying aqueous dispersions of nanoparticulate drug particles, wherein:

(a) the aqueous dispersions of nanoparticulate drug particles:

(i) comprise a poorly soluble crystalline drug, wherein by “poorly soluble” it is meant that the drug has a solubility in at least one liquid dispersion medium of less than about 10 mg/ml,

(ii) have an effective average particle size of less than about 1000 nm, meaning at least 50% of the drug particles have a particle size of less than about 1000 nm, and

(iii) have a surface modifier adsorbed on the surface thereof; and

(b) the aggregates of such spray-dried drug particle dispersions are less than or equal to about 100 microns in diameter; and

(c) such aggregates return to nanoparticulate drug particle dispersions upon reconstitution in an aqueous liquid medium.

12. (Original) The aerosol composition of claim 11 further comprising a diluent.

13. (Original) The aerosol composition of claim 12, wherein essentially every diluent particle comprises at least one embedded nanoparticulate drug particle having a surface modifier adhered to the surface of the drug particle.

14. (Original) The aerosol composition of claim 11, wherein the drug is selected from the group consisting of proteins, peptides, elastase inhibitors, analgesics, cystic-fibrosis therapies, asthma therapies, emphysema therapies, respiratory distress syndrome therapies, chronic bronchitis therapies, chronic obstructive pulmonary disease therapies, organ-transplant rejection therapies, therapies for tuberculosis and other infections of the lung, fungal infection therapies, and respiratory illness therapies associated with acquired immune deficiency syndrome, an oncology drug, an anti-emetic, and a cardiovascular agent.
15. (Previously Presented) The aerosol composition of claim 11, wherein the nanoparticulate drug particles have an effective average particle size of less than about 400 nm.
16. (Original) The aerosol composition of claim 11, wherein the aerosol comprises a concentration of a drug in an amount of from about 0.05 mg/g up to about 900 mg/g.
17. (Original) The aerosol composition of claim 16, wherein the aerosol comprises a concentration of a drug selected from the group consisting of about 10 mg/g or more, about 100 mg/g or more, about 200 mg/g or more, about 400 mg/g or more, about 600 mg/g or more, and about 900 mg/g.
18. (Previously Presented) The aerosol composition of claim 11, wherein the aggregates of the nanoparticulate drug particles have a mass median aerodynamic diameter of about 2 to about 10 microns.
19. (Previously Presented) The aerosol composition of claim 18, wherein the aggregates of the nanoparticulate drug particles have a mass median aerodynamic diameter of about 2 to about 6 microns.
20. (Previously Presented) The aerosol composition of claim 11, wherein the aggregates of the nanoparticulate drug particles have a mass median aerodynamic diameter of less than about 2 microns.

21. (Previously Presented) The aerosol composition of claim 11, wherein the aggregates of the nanoparticulate drug particles have a mass median aerodynamic diameter of about 5 to about 100 μm .

22. (Previously Presented) The aerosol composition of claim 21, wherein the aggregates of the nanoparticulate drug particles have a mass median aerodynamic diameter of about 30 to about 60 μm .

23. (Previously presented) A dry powder aerosol composition for pulmonary or nasal delivery comprising spherically shaped aggregates formed from freeze-drying aqueous dispersions of nanoparticulate drug particles, wherein:

- (a) the aggregates of such freeze-dried drug particle dispersions are less than or equal to about 100 microns in diameter;
- (b) the aqueous dispersions of nanoparticulate drug particles:
 - (i) comprise a poorly soluble crystalline drug, wherein by “poorly soluble” it is meant that the drug has a solubility in at least one liquid dispersion medium of less than about 10 mg/ml,
 - (ii) have an effective average particle size of less than about 1000 nm, meaning at least 50% of the drug particles have a particle size of less than about 1000 nm, and
 - (iii) have a surface modifier adsorbed on the surface thereof; and
- (c) such aggregates return to nanoparticulate drug particle dispersions upon reconstitution in an aqueous liquid medium.

24. (Original) The aerosol composition of claim 23, further comprising a diluent.

25. (Previously Presented) The aerosol composition of claim 23, wherein the drug is selected from the group consisting of proteins, peptides, elastase inhibitors, analgesics, cystic-fibrosis therapies, asthma therapies, emphysema therapies, respiratory distress syndrome therapies, chronic bronchitis

therapies, chronic obstructive pulmonary disease therapies, organ-transplant rejection therapies, therapies for tuberculosis and other infections of the lung, fungal infection therapies, and respiratory illness therapies associated with acquired immune deficiency syndrome, an oncology drug, an anti-emetic, and a cardiovascular agent.

26. (Previously Presented) The aerosol composition of claim 23, wherein the nanoparticulate drug particles have an effective average particle size of less than about 400 nm.

27. (Original) The aerosol composition of claim 23, wherein the aerosol comprises a concentration of a drug in an amount of from about 0.05 mg/g up to about 900 mg/g.

28. (Original) The aerosol composition of claim 27, wherein the aerosol comprises a concentration of a drug selected from the group consisting of about 10 mg/g or more, about 100 mg/g or more, about 200 mg/g or more, about 400 mg/g or more, about 600 mg/g or more, and about 900 mg/g.

29. (Previously Presented) The aerosol composition of claim 23, wherein the aggregates of the nanoparticulate drug particles have a mass median aerodynamic diameter of about 2 to about 10 microns.

30. (Previously Presented) The aerosol composition of claim 29, wherein the aggregates of the nanoparticulate drug particles have a mass median aerodynamic diameter of about 2 to about 6 microns.

31. (Previously Presented) The aerosol composition of claim 23, wherein the aggregates of the nanoparticulate drug particles have a mass median aerodynamic diameter of less than about 2 microns.

32. (Previously Presented) The aerosol composition of claim 23, wherein the aggregates of the nanoparticulate drug particles have a mass median aerodynamic diameter of about 5 to about 100 μ m.

33. (Previously Presented) The aerosol composition of claim 32, wherein the aggregates of the nanoparticulate drug particles have a mass median aerodynamic diameter of about 30 to about 60 μm .

34. (Original) The aerosol composition of claim 23, further comprising spray-dried nanoparticulate drug powder, wherein the drug of the freeze-dried nanoparticulate drug powder is either the same or different from the drug of the spray-dried nanoparticulate drug powder.

35. (Previously presented) A dry powder nanoparticulate aerosol composition for use in a propellant-based pMDI comprising

(a) spherically shaped aggregates of a nanoparticulate poorly soluble crystalline drug particles, wherein by “poorly soluble” it is meant that the drug has a solubility in at least one liquid dispersion medium of less than about 10 mg/ml, wherein the aggregates are less than or equal to about 100 microns in diameter, wherein such aggregates return to nanoparticulate drug particles upon reconstitution in an aqueous liquid medium, and wherein the drug particles:

(i) have a surface modifier adsorbed on the surface thereof, and

(ii) have an effective average particle size of less than about 1000 nm, meaning at least 50% of the drug particles have a particle size of less than about 1000 nm, and

(b) a non-aqueous propellant.

36. (Original) The aerosol composition of claim 35, wherein the propellant is a non-CFC propellant.

37. – 39. (Cancelled)

40. (Previously presented) A method of making a dry powder nanoparticulate drug composition comprising:

(a) forming an aqueous nanoparticulate dispersion of a poorly soluble drug, wherein:

- (i) the dispersion comprises poorly soluble crystalline drug particles and a surface modifier adsorbed on the surface thereof, wherein by “poorly soluble” it is meant that the drug has a solubility in the liquid dispersion medium of less than about 10 mg/ml, and
 - (ii) the drug particles have an effective average particle size of less than about 1000 nm, meaning at least 50% of the drug particles have a particle size of less than about 1000 nm; and
- (b) spray-drying the nanoparticulate dispersion to form a dry powder of spherically shaped aggregates of the nanoparticulate drug and surface modifier particles, wherein the aggregates have a diameter of less than or equal to about 100 microns, and wherein such aggregates return to a nanoparticulate drug dispersion upon reconstitution in an aqueous liquid medium.

41. (Original) The method of claim 40, further comprising adding a diluent to the nanoparticulate dispersion prior to spray-drying, wherein following spray-drying essentially every diluent particle contains at least one embedded drug particle and a surface modifier.

42. (Previously presented) A method of making a dry powder nanoparticulate drug aerosol formulation comprising:

- (a) milling under non-pressurized conditions in a non-aqueous medium having a high boiling point a dispersion comprising the following:
 - (i) a poorly soluble crystalline drug, wherein by “poorly soluble” it is meant that the drug has a solubility in the non-aqueous medium of less than about 10 mg/ml, and

- (ii) a surface modifier, to obtain a nanoparticulate drug composition having an effective average particle size of less than about 1000 nm, meaning at least 50% of the drug particles have a particle size of less than about 1000 nm, and
- (b) evaporating the non-aqueous medium to obtain a dry powder of spherically shaped aggregates of drug and surface modifier particles, wherein the aggregates have a diameter of less than or equal to about 100 microns, and wherein such aggregates return to nanoparticulate drug particle dispersions upon reconstitution in an aqueous liquid medium.

43. (Previously presented) A method of making an aerosol composition comprising:

- (a) milling under pressurized conditions in a non-aqueous medium a dispersion comprising the following:
 - (i) a poorly soluble crystalline drug, wherein by “poorly soluble” it is meant that the drug has a solubility in the non-aqueous dispersion medium of less than about 10 mg/ml, and
 - (ii) a surface modifier, to obtain a drug having an effective average particle size of less than about 1000 nm, meaning at least 50% of the drug particles have a particle size of less than about 1000 nm;
- (b) evaporating the non-aqueous medium to obtain a dry powder of spherically shaped aggregates of drug and surface modifier particles, wherein the aggregates have a diameter of less than or equal to about 100 microns, and wherein such aggregates return to nanoparticulate drug particle dispersions upon reconstitution in an aqueous liquid medium; and
- (c) formulating the dry powder spherically shaped aggregates into an aerosol composition.

44. (Previously presented) A method of making a dry powder nanoparticulate drug composition comprising:

(a) forming an aqueous nanoparticulate dispersion of a poorly soluble drug, wherein:

(i) the dispersion comprises poorly soluble crystalline drug particles, wherein by “poorly soluble” it is meant that the drug has a solubility in the liquid dispersion medium of less than about 10 mg/ml, and wherein the drug particles have an effective average particle size of less than about 1000 nm, meaning at least 50% of the drug particles have a particle size of less than about 1000 nm, and

(ii) a surface modifier adsorbed on the surface thereof; and

(b) freeze-drying the nanoparticulate dispersion to form a dry powder of spherically shaped aggregates of the nanoparticulate drug and surface modifier particles, wherein the aggregates have a diameter of less than or equal to about 100 microns, and wherein such aggregates return to nanoparticulate drug particle dispersions upon reconstitution in an aqueous liquid medium.

45. (Original) The method of claim 44, further comprising adding a diluent to the nanoparticulate dispersion prior to freeze-drying, wherein following freeze-drying essentially every diluent particle contains at least one embedded drug particle and a surface modifier.

46. (Cancelled).

47. (Original) A method of administering the aerosol of claim 11 to a patient, wherein the aerosol comprises drug at a concentration of 10 mg/g or greater, and wherein the patient delivery time for the aerosol administration is about 15 seconds or less.

48. (Original) A method of administering the aerosol of claim 23 to a patient, wherein the aerosol comprises drug at a concentration of 10 mg/g or greater, and wherein the patient delivery time for the aerosol administration is about 15 seconds or less.

49. (Original) A method of administering the aerosol of claim 35 to a patient, wherein the aerosol comprises drug at a concentration of 10 mg/g or greater, and wherein the patient delivery time for the aerosol administration is about 15 seconds or less.

50. (Cancelled).

51. (Previously Presented) The aerosol composition of claim 11, wherein the nanoparticulate drug particles have an effective average particle size of less than about 300 nm.

52. (Previously Presented) The aerosol composition of claim 11, wherein the nanoparticulate drug particles have an effective average particle size of less than about 250 nm.

53. (Previously Presented) The aerosol composition of claim 11, wherein the nanoparticulate drug particles have an effective average particle size of less than about 100 nm.

54. (Previously Presented) The aerosol composition of claim 11, wherein the nanoparticulate drug particles have an effective average particle size of less than about 50 nm.

55. (Previously Presented) The aerosol composition of claim 23, wherein the nanoparticulate drug particles have an effective average particle size of less than about 300 nm.

56. (Previously Presented) The aerosol composition of claim 23, wherein the nanoparticulate drug particles have an effective average particle size of less than about 250 nm.

57. (Previously Presented) The aerosol composition of claim 23, wherein the nanoparticulate drug particles have an effective average particle size of less than about 100 nm.

58. (Previously Presented) The aerosol composition of claim 23, wherein the nanoparticulate drug particles have an effective average particle size of less than about 50 nm.

59. (Previously Presented) The aerosol composition of claim 11, wherein at least 70% of the drug particles have a particle size of less than about 1000 nm.

60. (Previously Presented) The aerosol composition of claim 11, wherein at least 90% of the drug particles have a particle size of less than about 1000 nm.

61. (Previously Presented) The aerosol composition of claim 23, wherein at least 70% of the drug particles have a particle size of less than about 1000 nm.

62. (Previously Presented) The aerosol composition of claim 23, wherein at least 90% of the drug particles have a particle size of less than about 1000 nm.

63. (Previously Presented) The aerosol composition of claim 35, wherein at least 70% of the drug particles have a particle size of less than about 1000 nm.

64. (Previously Presented) The aerosol composition of claim 35, wherein at least 90% of the drug particles have a particle size of less than about 1000 nm.

65. (Previously Presented) The aerosol composition of claim 42, wherein at least 70% of the drug particles have a particle size of less than about 1000 nm.

66. (Previously Presented) The aerosol composition of claim 42, wherein at least 90% of the drug particles have a particle size of less than about 1000 nm.

67. (Previously Presented) The aerosol composition of claim 43, wherein at least 70% of the drug particles have a particle size of less than about 1000 nm.

68. (Previously Presented) The aerosol composition of claim 43, wherein at least 90% of the drug particles have a particle size of less than about 1000 nm.

69. (Previously Presented) The aerosol composition of claim 44, wherein at least 70% of the drug particles have a particle size of less than about 1000 nm.

70. (Previously Presented) The aerosol composition of claim 44, wherein at least 90% of the drug particles have a particle size of less than about 1000 nm.

71. (Previously Presented) The aerosol composition of claim 19, wherein the drug is selected from the group consisting of proteins, peptides, elastase inhibitors, analgesics, cystic-fibrosis therapies, asthma therapies, emphysema therapies, respiratory distress syndrome therapies, chronic bronchitis therapies, chronic obstructive pulmonary disease therapies, organ-transplant rejection therapies, therapies for tuberculosis and other infections of the lung, fungal infection therapies, and respiratory illness therapies associated with acquired immune deficiency syndrome, an oncology drug, an anti-emetic, and a cardiovascular agent.

72. (Previously Presented) The aerosol composition of claim 19, wherein the nanoparticulate drug particles have an effective average particle size selected from the group consisting of less than about 400 nm, less than about 300 nm, less than about 250 nm, less than about 100 nm, and less than about 50 nm.

73. (Previously Presented) The aerosol composition of claim 20, wherein the drug is selected from the group consisting of proteins, peptides, elastase inhibitors, analgesics, cystic-fibrosis therapies, asthma therapies, emphysema therapies, respiratory distress syndrome therapies, chronic bronchitis therapies, chronic obstructive pulmonary disease therapies, organ-transplant rejection therapies, therapies for tuberculosis and other infections of the lung, fungal infection therapies, and respiratory

illness therapies associated with acquired immune deficiency syndrome, an oncology drug, an anti-emetic, and a cardiovascular agent.

74. (Previously Presented) The aerosol composition of claim 20, wherein the nanoparticulate drug particles have an effective average particle size selected from the group consisting of less than about 400 nm, less than about 300 nm, less than about 250 nm, less than about 100 nm, and less than about 50 nm.

75. (Previously Presented) The aerosol composition of claim 22, wherein the drug is selected from the group consisting of proteins, peptides, elastase inhibitors, analgesics, cystic-fibrosis therapies, asthma therapies, emphysema therapies, respiratory distress syndrome therapies, chronic bronchitis therapies, chronic obstructive pulmonary disease therapies, organ-transplant rejection therapies, therapies for tuberculosis and other infections of the lung, fungal infection therapies, and respiratory illness therapies associated with acquired immune deficiency syndrome, an oncology drug, an anti-emetic, and a cardiovascular agent.

76. (Previously Presented) The aerosol composition of claim 22, wherein the nanoparticulate drug particles have an effective average particle size selected from the group consisting of less than about 400 nm, less than about 300 nm, less than about 250 nm, less than about 100 nm, and less than about 50 nm.

77. (Previously Presented) The aerosol composition of claim 30, wherein the drug is selected from the group consisting of proteins, peptides, elastase inhibitors, analgesics, cystic-fibrosis therapies, asthma therapies, emphysema therapies, respiratory distress syndrome therapies, chronic bronchitis therapies, chronic obstructive pulmonary disease therapies, organ-transplant rejection therapies, therapies for tuberculosis and other infections of the lung, fungal infection therapies, and respiratory

illness therapies associated with acquired immune deficiency syndrome, an oncology drug, an anti-emetic, and a cardiovascular agent.

78. (Previously Presented) The aerosol composition of claim 30, wherein the nanoparticulate drug particles have an effective average particle size selected from the group consisting of less than about 400 nm, less than about 300 nm, less than about 250 nm, less than about 100 nm, and less than about 50 nm.

79. (Previously Presented) The aerosol composition of claim 31, wherein the drug is selected from the group consisting of proteins, peptides, elastase inhibitors, analgesics, cystic-fibrosis therapies, asthma therapies, emphysema therapies, respiratory distress syndrome therapies, chronic bronchitis therapies, chronic obstructive pulmonary disease therapies, organ-transplant rejection therapies, therapies for tuberculosis and other infections of the lung, fungal infection therapies, and respiratory illness therapies associated with acquired immune deficiency syndrome, an oncology drug, an anti-emetic, and a cardiovascular agent.

80. (Previously Presented) The aerosol composition of claim 31, wherein the nanoparticulate drug particles have an effective average particle size selected from the group consisting of less than about 400 nm, less than about 300 nm, less than about 250 nm, less than about 100 nm, and less than about 50 nm.

81. (Previously Presented) The aerosol composition of claim 33, wherein the drug is selected from the group consisting of proteins, peptides, elastase inhibitors, analgesics, cystic-fibrosis therapies, asthma therapies, emphysema therapies, respiratory distress syndrome therapies, chronic bronchitis therapies, chronic obstructive pulmonary disease therapies, organ-transplant rejection therapies, therapies for tuberculosis and other infections of the lung, fungal infection therapies, and respiratory

illness therapies associated with acquired immune deficiency syndrome, an oncology drug, an anti-emetic, and a cardiovascular agent.

82. (Previously Presented) The aerosol composition of claim 33, wherein the nanoparticulate drug particles have an effective average particle size selected from the group consisting of less than about 400 nm, less than about 300 nm, less than about 250 nm, less than about 100 nm, and less than about 50 nm.

83. (Previously Presented) The aerosol composition of claim 35, wherein the drug is selected from the group consisting of proteins, peptides, elastase inhibitors, analgesics, cystic-fibrosis therapies, asthma therapies, emphysema therapies, respiratory distress syndrome therapies, chronic bronchitis therapies, chronic obstructive pulmonary disease therapies, organ-transplant rejection therapies, therapies for tuberculosis and other infections of the lung, fungal infection therapies, and respiratory illness therapies associated with acquired immune deficiency syndrome, an oncology drug, an anti-emetic, and a cardiovascular agent.

84. (Previously Presented) The aerosol composition of claim 35, wherein the nanoparticulate drug particles have an effective average particle size selected from the group consisting of less than about 400 nm, less than about 300 nm, less than about 250 nm, less than about 100 nm, and less than about 50 nm.

85. (Previously Presented) The aerosol composition of claim 35, wherein the aggregates of the nanoparticulate drug particles have a mass median aerodynamic diameter of about 2 to about 10 microns.

86. (Previously Presented) The aerosol composition of claim 85, wherein the aggregates of the nanoparticulate drug particles have a mass median aerodynamic diameter of about 2 to about 6 microns.

87. (Previously Presented) The aerosol composition of claim 35, wherein the aggregates of the nanoparticulate drug particles have a mass median aerodynamic diameter of less than about 2 microns.
88. (Previously Presented) The aerosol composition of claim 35, wherein the aggregates of the nanoparticulate drug particles have a mass median aerodynamic diameter of about 5 to about 100 μm .
89. (Previously Presented) The aerosol composition of claim 88, wherein the aggregates of the nanoparticulate drug particles have a mass median aerodynamic diameter of about 30 to about 60 μm .
90. (Previously Presented) The method of claim 40, wherein the drug is selected from the group consisting of proteins, peptides, elastase inhibitors, analgesics, cystic-fibrosis therapies, asthma therapies, emphysema therapies, respiratory distress syndrome therapies, chronic bronchitis therapies, chronic obstructive pulmonary disease therapies, organ-transplant rejection therapies, therapies for tuberculosis and other infections of the lung, fungal infection therapies, and respiratory illness therapies associated with acquired immune deficiency syndrome, an oncology drug, an anti-emetic, and a cardiovascular agent.
91. (Previously Presented) The method of claim 40, wherein the nanoparticulate drug particles have an effective average particle size selected from the group consisting of less than about 400 nm, less than about 300 nm, less than about 250 nm, less than about 100 nm, and less than about 50 nm.
92. (Previously Presented) The method of claim 40, wherein the aggregates of the nanoparticulate drug particles have a mass median aerodynamic diameter of about 2 to about 10 microns.
93. (Previously Presented) The method of claim 92, wherein the aggregates of the nanoparticulate drug particles have a mass median aerodynamic diameter of about 2 to about 6 microns.

94. (Previously Presented) The method of claim 40, wherein the aggregates of the nanoparticulate drug particles have a mass median aerodynamic diameter of less than about 2 microns.

95. (Previously Presented) The method of claim 40, wherein the aggregates of the nanoparticulate drug particles have a mass median aerodynamic diameter of about 5 to about 100 μm .

96. (Previously Presented) The method of claim 95, wherein the aggregates of the nanoparticulate drug particles have a mass median aerodynamic diameter of about 30 to about 60 μm .

97. (Previously Presented) The method of claim 42, wherein the drug is selected from the group consisting of proteins, peptides, elastase inhibitors, analgesics, cystic-fibrosis therapies, asthma therapies, emphysema therapies, respiratory distress syndrome therapies, chronic bronchitis therapies, chronic obstructive pulmonary disease therapies, organ-transplant rejection therapies, therapies for tuberculosis and other infections of the lung, fungal infection therapies, and respiratory illness therapies associated with acquired immune deficiency syndrome, an oncology drug, an anti-emetic, and a cardiovascular agent.

98. (Previously Presented) The method of claim 42, wherein the nanoparticulate drug particles have an effective average particle size selected from the group consisting of less than about 400 nm, less than about 300 nm, less than about 250 nm, less than about 100 nm, and less than about 50 nm.

99. (Previously Presented) The method of claim 42, wherein the aggregates of the nanoparticulate drug particles have a mass median aerodynamic diameter of about 2 to about 10 microns.

100. (Previously Presented) The method of claim 99, wherein the aggregates of the nanoparticulate drug particles have a mass median aerodynamic diameter of about 2 to about 6 microns.

101. (Previously Presented) The method of claim 42, wherein the aggregates of the nanoparticulate drug particles have a mass median aerodynamic diameter of less than about 2 microns.

102. (Previously Presented) The method of claim 42, wherein the aggregates of the nanoparticulate drug particles have a mass median aerodynamic diameter of about 5 to about 100 μm .

103. (Previously Presented) The method of claim 102, wherein the aggregates of the nanoparticulate drug particles have a mass median aerodynamic diameter of about 30 to about 60 μm .

104. (Previously Presented) The method of claim 43, wherein the drug is selected from the group consisting of proteins, peptides, elastase inhibitors, analgesics, cystic-fibrosis therapies, asthma therapies, emphysema therapies, respiratory distress syndrome therapies, chronic bronchitis therapies, chronic obstructive pulmonary disease therapies, organ-transplant rejection therapies, therapies for tuberculosis and other infections of the lung, fungal infection therapies, and respiratory illness therapies associated with acquired immune deficiency syndrome, an oncology drug, an anti-emetic, and a cardiovascular agent.

105. (Previously Presented) The method of claim 43, wherein the nanoparticulate drug particles have an effective average particle size selected from the group consisting of less than about 400 nm, less than about 300 nm, less than about 250 nm, less than about 100 nm, and less than about 50 nm.

106. (Previously Presented) The method of claim 43, wherein the aggregates of the nanoparticulate drug particles have a mass median aerodynamic diameter of about 2 to about 10 microns.

107. (Previously Presented) The method of claim 106, wherein the aggregates of the nanoparticulate drug particles have a mass median aerodynamic diameter of about 2 to about 6 microns.

108. (Previously Presented) The method of claim 43, wherein the aggregates of the nanoparticulate drug particles have a mass median aerodynamic diameter of less than about 2 microns.

109. (Previously Presented) The method of claim 43, wherein the aggregates of the nanoparticulate drug particles have a mass median aerodynamic diameter of about 5 to about 100 μm .

110. (Previously Presented) The method of claim 109, wherein the aggregates of the nanoparticulate drug particles have a mass median aerodynamic diameter of about 30 to about 60 μm .

111. (Previously Presented) The method of claim 44, wherein the drug is selected from the group consisting of proteins, peptides, elastase inhibitors, analgesics, cystic-fibrosis therapies, asthma therapies, emphysema therapies, respiratory distress syndrome therapies, chronic bronchitis therapies, chronic obstructive pulmonary disease therapies, organ-transplant rejection therapies, therapies for tuberculosis and other infections of the lung, fungal infection therapies, and respiratory illness therapies associated with acquired immune deficiency syndrome, an oncology drug, an anti-emetic, and a cardiovascular agent.

112. (Previously Presented) The method of claim 44, wherein the nanoparticulate drug particles have an effective average particle size selected from the group consisting of less than about 400 nm, less than about 300 nm, less than about 250 nm, less than about 100 nm, and less than about 50 nm.

113. (Previously Presented) The method of claim 44, wherein the aggregates of the nanoparticulate drug particles have a mass median aerodynamic diameter of about 2 to about 10 microns.

114. (Previously Presented) The method of claim 113, wherein the aggregates of the nanoparticulate drug particles have a mass median aerodynamic diameter of about 2 to about 6 microns.

115. (Previously Presented) The method of claim 44, wherein the aggregates of the nanoparticulate drug particles have a mass median aerodynamic diameter of less than about 2 microns.

116. (Previously Presented) The method of claim 44, wherein the aggregates of the nanoparticulate drug particles have a mass median aerodynamic diameter of about 5 to about 100 μm .

117. (Previously Presented) The method of claim 116, wherein the aggregates of the nanoparticulate drug particles have a mass median aerodynamic diameter of about 30 to about 60 μm .

118. (Previously Presented) The aerosol composition of any one of claims 14, 25, 71, 73, 75, 77, 79, 81, or 83 wherein the drug is selected from the group consisting of a bronchodilator, a corticosteroid, and an anti-fungal.

119. (Previously Presented) The method of any one of claims 90, 97, 104, and 111, wherein the drug is selected from the group consisting of a bronchodilator, a corticosteroid, and an anti-fungal.

120. (Previously Presented) The aerosol composition of claim 14, wherein the drug is selected from the group consisting of beclomethasone dipropionate, naproxen, triamcinolone acetonide, budesonide, and an anti-emetic.

121. (Previously Presented) The aerosol composition of claim 25, wherein the drug is selected from the group consisting of beclomethasone dipropionate, naproxen, triamcinolone acetonide, budesonide, and an anti-emetic.

IX. EVIDENCE APPENDIX

Appellants append copies of the following evidence that was introduced and entered into the record during prosecution:

I. METERED VS. NONMETERED SYSTEMS

Devices which can be used to generate inhalation aerosols fall into two main categories: those which purport to meter the drug dose provided to the patient and those which do not. Because the formulation of metered dose inhalers or MDIs presents the pharmaceutical scientist with some unique challenges, these devices are described separately in another chapter. The present chapter attempts to come to grips with the principles of operation of continuous aerosol generators and their use in the treatment of human disease. These devices, of which nebulizers are the most common example, are used widely by pharmacologists involved with drug testing in animals and are increasingly seen as a useful adjunct to MDI therapy in humans. Despite the implication in the chapter title that nebulizers provide an unknown dose, they can be used conveniently by researchers who seek to establish the dosimetry of compounds delivered to the lungs. This step is a necessity in the development phase for a new drug entity and should be performed prior to the formulation and design of metered dose units. While the majority of this chapter is concerned with the use of continuous aerosol generators to administer drugs in a therapeutic setting, two sections (I.L.C. and V.C.) address the subject of assigning a value for "dose to the lung" applicable to a drug development protocol.

Some of the advantages and disadvantages of nonmetered systems such as portable nebulizers are listed in Table 1. In view of the fact that aerosols are presently inhaled mostly by breathing-impaired patients, the predominant factor dictating the use of a nebulizer over an MDI is patient preference. Nebulizers offer the possibility of tidal inhalation and exhalation (as opposed to deep inhalation and breath-hold, phased with actuation for optimal MDI usage). However, in view of the fact that some new compounds may be administered to lung-normal patients (for systemic delivery perhaps), this factor is drug and disease specific. From a technological point of view, the possibility of administering much larger doses by employing continuous aerosol inhalation is the nebulizer's most appealing advantage. Disadvantages, on the other hand, are many; the level of patient education is critical if hygiene is to be maintained and, because of the complexity associated with these devices, much of the control remains in the hands of the patient. The wide variety of available devices and their different specifications makes misuse a likely occurrence.

II. ESTIMATING DOSIMETRY

Only a basic understanding of the factors affecting aerosol deposition in the lung is necessary in order to realize that neither continuous generators nor so-called "metered dose inhalers" really control the drug dose reaching the airways of the lung. It is true that the MDI limits the amount a patient can inhale from a single actuation of the inhaler, but in neither this case, nor that of the nebulizer, will all of the aerosolized material reach and deposit in the lung. While it is not the intention to review deposition in detail (see Chapter 1), the importance of defining dosimetry in terms of drug mass requires that a simple mass-based deposition model be presented here as a precursor to later arguments to be used in this and the next chapter.

A. STABLE AEROSOLS INHALED BY NORMAL HUMANS

When discussing the different categories of generation and delivery device, it is helpful to keep a simple model of aerosol deposition in mind. Aerosol size distribution is the single most important variable in defining the site of droplet or particle deposition in the patient; in short, it will determine whether drug targeting succeeds or fails. From a pharmacological point of view, the most important parameter is usually the mass median aerodynamic diameter (MMAD) of an aerosol. This is the aerodynamic diameter above and below which 50% of the mass resides. Aerodynamic diameter is the diameter of a unit density sphere which behaves in air in the same way as the droplet or particle in question. In the frequent event that MMAD is determined by

Advantages

1. Large sample size
2. Patient preference
3. Water is usually the solvent
4. Patient coordination is not usually a problem

- In the home, in public places, smaller devices like MP3s are usually preferred.
- Popularity and customer loyalty is not as high.

$$d_s = (\text{actual diameter}) (\text{density})^{1/3} \quad (1)$$

Different aerosol size distributions may be expected to deposit preferentially in different regions of the respiratory tract. Aerosols inhaled through the nose have different deposition patterns to those inhaled orally.¹ In Figure 1, oral inhalation by normal subjects is assumed because this is the more frequent mode of inhalation. Fractional deposition (in terms of particle mass or droplet mass) is shown for monodisperse, stable aerosols. The data in support of Figure 1 are derived from human exposure to radiolabelled stable aerosols with subjects inhaling and exhaling steadily.^{2,3} If the horizontal axis on Figure 1 were labeled "mass median aerodynamic diameter" so that polydisperse aerosols were considered,⁴ the curves indicating deposition in the lung may be reduced in height, indicating less efficient deposition, but the maxima would remain at the same diameters.⁵ In normal subjects, deposition in the pulmonary or alveolar compartment is slow optimal for aerosols with aerodynamic diameters around 2 to 3 μm provided inhalation is slow (20 to 30 l/min).⁶ Maximum deposition in the tracheobronchial regions occurs with slightly

FIGURE 1. Estimated fractional mass deposition, f_d , vs. aerodynamic diameter (μm) in peripheral or mouth (M), tracheobronchial region (TB), and pulmonary region with ($P+bb$) and without breath-hold ($P-bb$). Deposition is for stable aerosolized particles inhaled by normal human breathing steadily with inspiratory flow rates of 22 l/min. Polydisperse aerosols produce similar curves with lower maxima when mean aerodynamic diameter is plotted on the horizontal axis. (Reprinted with permission of the American Pharmaceutical Association.)

larger particles, although mucociliary clearance can remove material quite quickly from this region (Chapter 6).

B. BREATHING PATTERN AND DISEASE

The curve maxima in Figure 1 shift on both axes if the breathing pattern is changed. With faster inhalation, smaller aerosols usually deposit higher in the respiratory tract (tracheobronchial deposition is enhanced) than would be the case if inhalation were slow. In part this is due to increased turbulence. The tracheobronchial or conducting airways extend down to the terminal bronchioles. Constriction of the tracheobronchial airways is responsible for most of the breathing difficulty in reversible asthma. Unlike the pulmonary region, these airways have smooth muscle in their walls. It is obvious that aerosol deposition in an asthmatic individual will be different from that in a normal subject. Partly due to turbulence in constricted airways but also because the aerosol cannot penetrate well into poorly ventilated areas, deposition tends to occur more centrally in patients than it does in normal subjects.¹² Also, intersubject variations in deposition are much larger in the diseased population. This variability in aerosol deposition, which the pathophysiology of asthma creates,¹² obscures many of the finer differences resulting from aerosol size changes and breathing pattern. Even so, the trends shown in Figure 1 remain broadly true. Aerosol particles with larger aerodynamic diameters have an increased tendency to collide with surfaces in their paths and separate by impaction in the upper airways. Smaller particles (which form more stable aerosols) tend to separate largely by sedimentation in the small, peripheral airways provided the airflow takes them there. The upper curve in Figure 1 shows an estimate of the increased deposition in the lung periphery resulting from breath-holding after inhalation.¹¹ If small particles ($\sim 2 \mu\text{m}$; Figure 1) do not reach the periphery, where the sedimentation distances become small enough for them to deposit during a breath-holding pause, then they are more likely to be exhaled.^{14,15} In the bronchoconstricted asthmatic, when airway narrowing is substantial, some small enhancement in deposition due to settling may be expected in the upper airways as a result of breath-holding.

C. PRINCIPLES OF DOSE ESTIMATION

Presumably, the drug formulator and product designer wish to deliver a known dose more or less reliably to the lungs of a patient. If we assume at this stage that it is possible to generate several tidal volumes of homogeneously distributed aerosol and make this available as the subject's mouth, in principle it is then possible for the formulator to estimate the dose administered to the lungs. Several basics should be standardized and have known values. These are

1. Drug concentration in air
2. Aerosol size distribution (drug MMAD and a measure of polydispersity)
3. The subject's breathing pattern (rate and frequency of inspiration, duration of breath-hold, and inhaled volume)

Then, let us assume that a well-trained, "long-normal" subject inhales at a known rate, say 20 to 30 l/min, and breath-holds for a chosen interval. Assume further that he or she inhales a tidal volume of aerosol equal to 3 l on 4 separate inhalations. If the aerosol size is known, then it is usually possible to choose an appropriate deposition model and assign a value to mass fractional deposition, f_d (Figure 1). This may be in the whole lung (TB + P, Figure 1) or a portion of it, as described in an earlier chapter, whichever is considered to be most important. The product of the aerosol concentration and inhaled volume then provides an estimate of the drug mass inhaled which, when multiplied by f_d , gives the estimated dose deposited. While some of the deficiencies of this approach are discussed later in Section V.C, it is apparent that the aerosol formulator and device designer must work closely together to produce a combination which delivers drug in aerosolized form with an appropriate concentration and particle size distribution so as to optimize its mass deposition in the respiratory tract. The aerosol concentration and size distribution which matters is the one which the patient sees at his or her oropharynx, and is not necessarily the one which was determined perhaps 1 m of tubing before reaching the patient. Although it is difficult to achieve, the ideal aerosol should be presented to the patient as a stationary, stable cloud of particles or droplets suspended in air.

III. DYNAMICS OF INHALATION AEROSOLS

An understanding of three important phenomena which affect aerosol size and concentration are required prior to explaining the performance characteristics of different devices. An understanding of particle or droplet impaction, sedimentation, and solvent evaporation or condensation kinetics is essential to the design of successful administration systems. These three phenomena (impaction, sedimentation, and the size changes induced by evaporation or condensation) stand out from others in aerosol physics (thermophoresis, photophoresis, and particle diffusion, for example) as being the primary mechanisms by which aerosolized medications separate and/or change their particle size distributions most rapidly within delivery systems. Each topic is described briefly in turn.

A. DROPLET OR PARTICLE IMPACTION

Aerosol segregation on the basis of the inertial properties of the dispersed phase is important not only to explain deposition in the upper airways (Chapter I), but also to understand some of the principles by which inhalation devices function and, in some cases, fail to function. It is necessary to gain a simple understanding of the process (which is also used as the principle of operation for cascade impactors) sufficient to be able to say when droplet impaction is or is not likely to occur. Figure 2 is a schematic showing aerosol passage within a circular tube of internal diameter, W . The large droplet is shown leaving the airflow and impacting while the smaller one deviates with the airflow. In order to simplify the theory, the distance from the end of the tube

to the impaction surface is held equal to $1/2$ the width of the tube, W , and is thus equal to the maximum distance a particle or droplet traveling down its center must deviate from the airflow in order to collide with the surface in its path. Figure 2 also shows a typical plot of impaction efficiency as a function of the dimensionless Stokes' number, Stk , which, for unit density spheres $> 1 \mu\text{m}$ in diameter, in air at 1 atm and 20°C , can be written in the centimeter-gram-second system as:

$$Stk = V d^2 / (0.00165 W) \quad (2)$$

where V is the linear velocity of the airflow and d is droplet diameter. Because \sqrt{Stk} is often ≈ 0.5 ($Stk = 0.25$) for a 50% probability of impaction occurring (Figure 2), it is a simple matter to calculate the approximate linear velocity at which a droplet of known diameter will impact in an arrangement like that shown in Figure 2. If, for example, W were 1 cm and $d = 5 \mu\text{m}$ (or $5 \times 10^{-4} \text{ cm}$) then the critical velocity for a 50% chance of impaction would be

$$V_{50} = 0.25 \times 0.00165 \times 1 / (5 \times 10^{-4})^2 = 1630 \text{ cm/s} \quad (3)$$

or 16.3 cm/s. In order to increase impaction of smaller droplets in this set up, greater velocities are necessary. Alternatively, the value of $0.5 \times W$ (the distance the droplet needs to deviate from the airflow) can be made smaller. Calculations of this type are relevant to baffle design in jet nebulizers and particle deposition from MDIs. They can also be used to explain why impaction is only a major mechanism of deposition in the upper airways of the lung where the linear airflow velocities remain high.

5. SEDIMENTATION

Table 2 shows sedimentation velocities of unit density spheres in still air at 20°C . The values only make meaning when used in conjunction with aerosol residence times in containers of known dimensions. Consider, for example, an aerosol flowing horizontally at 5 l/min along a 30 cm tube with an internal diameter equal to 2 cm. The linear airflow velocity is given by (volume flow rate)/(area) or $(5000 \text{ cm}^3/\text{min}) / (\pi \text{ cm}^2) = 1592 \text{ cm} / \text{min}$. The residence time in 30 cm of tubing $(30 \text{ cm} / 1592 \text{ cm min}^{-1} = 0.0189 \text{ min})$ is thus 1.13 s. Because a $10\text{-}\mu\text{m}$ sphere can settle 0.33 cm in this residence time, about 18% of $10\text{-}\mu\text{m}$ spheres will be deposited in the tube during the passage of the aerosol. This percentage is a function of droplet size and can be

estimated quite simply from the ratio of distance settled to the residence time to the internal diameter of the tubing. Although these arguments neglect to account for turbulent mixing, they can be extended to their logical conclusions which are frequently found in practice to be correct. There are three main results of passing polydispersed aerosols in our size range of interest (Figure 1) along tubes. The segregation induced by the sedimentation process ensures that the aerosol flowing from the tubing outlet has (1) decreased concentration, (2) a smaller median diameter, and (3) decreased "polydispersity". The relative magnitude of all these segregation effects becomes smaller as the aerosol droplet or particle size is reduced as the inlet to the tube because the aerosol becomes "more stable" and is less likely to sediment quickly. The "polydispersity" of the aerosol distribution refers to the magnitude of the spread of the particle size distribution. It is frequently characterized numerically as the geometric standard deviation (GSD) of log-normally distributed aerosols.⁹ Some of these effects are shown in our work designed to determine drug absorption kinetics after characterized aerosol administration to dogs.^{14,15} As they were generated, the aerosols of three median sizes were all significantly polydispersed (GSD = 2). After passage along the tubes required for administration by positive pressure ventilation, however, segregation caused the larger aerosols (3.5 and 4 μm MMAD) to tend toward monodispersity (GSD = 1.3). This effect was much less for the smallest aerosol (1.0 μm MMAD) which was administered after passage through the same apparatus, with a GSD equal to 1.6.¹⁵

C. EVAPORATION AND CONDENSATION

Therapeutic aerosols are unstable in two major respects. First, they contain droplets or particles which are too large to stay in suspension for long. Second, they contain volatile or hygroscopic materials which cause aerosol size changes to occur as a function of time, temperature, aerosol dilution, and droplet or particle content. The thermodynamics and kinetics of this latter subject are too complex to consider in detail here, even when single particles or droplets are considered. In simple terms, and as far as therapeutic aerosols are concerned, two questions are of importance:

1. How fast can evaporation or condensation alter the particle size distribution of an aerosol?
2. How much can they change the size distribution (if they occur fast enough)?

The enormous surface:volume ratio presented by typical medicinal aerosols requires that we think of water as a volatile material and thus, a reasonable answer to the first question is "fast enough to worry about". The calculated lifetime of a 10- μm water droplet at 25°C and 60% relative humidity is only ~ 0.5 s¹⁶ and a breath of aerosol usually takes several seconds to inhale.¹ Furthermore, and with obvious relevance to MDIs, some of the solvents and propellants used

colated in the
x and can be

In therapeutic aerosols are more volatile than water. Thus, as a rule of thumb, we can often assume that aerosols adjust their size distributions extremely quickly. To answer the second question, droplets will grow or shrink until their solvent vapor pressures are in equilibrium with the environment. Different droplet "environments" may display a wide range of temperatures but rarely contain fluorocarbon or ethanol vapors in significant concentrations. While ingredients like these should be lost rapidly and completely, we will see the complexity of the subject in the following chapter, when we observe that inadequate heat transfer to supercooled propellant droplets ultimately slows and governs the rate at which the size of MDI generated aerosols can shrink to the respirable range.

Because atmospheric air, compressed air, and the air in the lung contain water vapor, the behavior of aqueous aerosols can vary as a function of the environmental humidity. Pure water aerosols will obviously tend to evaporate at all relative humidities less than 100%. At constant temperature, aqueous aerosols containing dissolved salts have a particular relative humidity with which they exist in equilibrium. At this relative humidity, which is roughly predictable from a consideration of Raoult's law and a psychrometric chart,¹² they show no tendency to grow or shrink. However, systems which are isotonic with blood are very dilute and tend to evaporate as they pass in dilution air from a nebulizer to the patient. The opposite occurs with some hypertonic solution and dry powder aerosols.¹ These often display hygroscopic growth in the humid environment of the lung.^{13,14} The relative humidity in the lung is in excess of 99% at 37°C.¹ This relative humidity would be that measured over a solution of isotonic saline at the same temperature. Water-soluble drugs administered as hypertonic solutions or solids, therefore, tend to grow rapidly as they pass through the humid environment of the respiratory tract.^{15,16} The size they try to attain during inhalation is defined theoretically by the aqueous droplet size which would contain a drug concentration isotonic with blood. These concentrations are often of the order of 1 to 5% showing that the growth tendency of a typical hygroscopic solid is to take on board about 20 to 100 times its own mass of water (employing hypertonic aerosols to enhance deposition in the lung has been advocated recently in the literature¹⁷). Because the diameter of a droplet is proportional to the cube root of its volume (and ignoring density considerations), a 20-fold growth in mass would correspond to an approximate growth ratio of (equilibrium diameter at lung humidity)/(dry particle diameter) = 20^{1/3} or 2.7. In practice during inhalation, ratios less than those predicted at equilibrium are operative because the process is dynamic. Nevertheless, this discussion shows the importance of paying careful attention to the various humidities which can be encountered in administration systems as well as the hygroscopic tendencies of some solid materials.

IV. AEROSOL GENERATION

There are two major types of nebulized inhalation device which are used largely for the treatment and prevention of respiratory disease. These are jet or ultrasonic nebulizers. In practice, neither of these have been well accepted for the delivery of therapeutic agents for systemic purposes. Systemic administration potential clearly exists, however, given the wide acceptance of this route for the administration of drugs of abuse. Inhalation offers rapid absorption opportunities for compounds which require fast onset. Furthermore, the anatomical arrangements of the major vessels are such that they could usefully be employed to target absorbed compounds to the heart.

Mainly over the last decade, the design and construction of devices has been improved in order to enhance the drug doses which can be delivered successfully to the breathing-impaired. The main improvements have been to increase the output of respirable aerosol. This has been achieved in two ways: first, by increasing total output concentrations and secondly, by reducing droplet or particle sizes emitted by nebulizers. Because of recent improvements in aerosol design and the usefulness of these latter devices for animal experimentation and

FIGURE 3. Mass of aerosolized dust from a dust generator (TSI, St. Paul, MN) supplied with dry air at 10 l/min. Aerosol concentrations approach constancy after approximately 3 h when averaged powder input to the fluid bed is balanced by aerosol output from the generator.

toxicity testing, the following discussion includes three major device categories. These are discussed in turn alongside some of the accessories which are commonly used with them: (1) dry powder generator, (2) air-blend nebulizers, and (3) ultrasonic nebulizers.

A. DRY POWDER GENERATORS

Dust generators have long been in existence, the most famous of which is probably the Wright Dust-Feed Apparatus.¹² However, these generators have historically been difficult to adapt to pharmaceutical studies. More recently, fluidized bed technology has improved to such an extent that generators are now available commercially which are capable of disaggregating powder charges and providing these as dispersions of powders in air.^{13,14} The dispersed dust can often be shown to possess the same size characteristics as the powder with which the bed was supplied.¹⁵ Thus, it is possible to micronize pharmaceutical powders, pass these into a bed of metal beads which are fluidized by dry air or gas which causes the beads to appear to "boil", and utilize the aerosol formed by the disaggregating action of the bed. Provided the bed is fed with powder continuously, a steady state is reached between powder input and aerosol output which demands that the aerosol output remains at a constant concentration (Figure 3). Steady-state concentrations of respirable aerosol ($<5 \mu\text{m}$ aerodynamic diameter), which can approach 1 mg/l under some circumstances, are several times higher from these devices than those which can be produced by other generators.¹⁶ The high concentrations are important for reasons described below. The devices themselves and their utilization have been described in more detail elsewhere.^{14,17} They are manufactured and marketed by TSI (St. Paul, MN).

Performance of inhalation dosimetry and toxicity studies usually requires dose ranging and is often severely limited by the maximum available aerosol concentration emitted by the chosen generator. This is especially true for pharmaceutical studies where it is important that the stability of the administered compound is maintained during aerosol generation. Condensation generators, for example, require vaporization of the chemical agent prior to its condensation as a high concentration aerosol.¹⁸ Such a procedure is usually unacceptable in pharmaceutical trials.¹⁹ The selection of a generator which provides the greatest output concentration is important for two main reasons. First, and most important, respiratory (as opposed to systemic) toxicity is extremely difficult to detect, yet it remains important, even in phase I studies of new

Index Terms

apparent density; bulk density; density; density ratio; metal powders; packed density; powder metallurgy; tap density

Autotap and Dual Autotap

The apparent densities of powdered, granular or flaked materials are highly dependent on the manner in which the particles are packed together. During tapping, smaller particles distribute into the spaces between larger particles. Gradually particles pack more efficiently, the powder volume decreases and the tap density increases, often by 50% to 100%.

For this measurement, Quantachrome has developed two instruments which conform to the British Pharmacopoeia method for Apparent Volume and ASTM standard test methods B527, D4164 and D4781 for Tap Density. These two models, the Autotap and the two sample Dual Autotap, automate the required procedures to provide accurate, reproducible values.

Samples are placed in standard graduated cylinders and mounted on a universal tap platform designed to accommodate cylinders from 10 ml to 1000 ml. Rotation of the tap platform facilitates reading by keeping a flat interface. After noting the initial volume and weight of the material, tapping is started.

If the material characteristic is unknown, tapping may be done continuously, or step-wise by user specified numbers of taps, while noting or graphing the results until the volume becomes constant. In either case the number of taps is displayed. Once the material characteristic is known the proper number of taps, typically thousands, can be preset on subsequent runs thus freeing the operator for other work.

Optimal Tapped Density Tester

Available in USP or ASTM versions, our dual platform Optimal Tap Density Testers offer a standardized and repeatable method for measuring tapped or packed volumes of powders and granulated or flaked materials. Our microprocessor controlled USP model features a rotating platform for simultaneous tapping and rotation of the cylinder to ensure a level reading. The USP version provides a 5/8-inch vertical drop per tap at 300 taps per minute and includes one 100 ml funnel top graduated cylinder per platform. Our ASTM version (which complies with the American Society for Testing and Materials Standards) features a non-rotating platform, a 1/8-inch vertical drop per tap at 250 taps per minute, and one 250 ml graduated funnel top cylinder per platform. ASTM method D4164-82 is for testing catalyst particles and requires a 250 ml cylinder and platform; B527-93 involves metallic powders and compounds and requires a 100 ml cylinder and platform.

All of our Tap Density Testers have digital LED displays and user selectable counter or timer operation. The embedded sealed membrane keypad is impervious to dust and particles and can be used to calculate density measurements. The units can be programmed to any number of taps or time period required. An optional thermal printer records program test conditions, time, date, and density measurements.

Tap Density Tester, USP 24 / NF 19

Includes dual rotating platform drive units and two 100 ml graduated funnel top cylinders (class B).

400-007 230V, 50Hz, dual platform, ASTM with 100 ml graduated cylinders

IAA24 are likely participants in auxin gene regulation through the TGCTC elements. A single copy of ER8 was a more active AuxRE than other constructs that contained two copies of TGCTC (3, 11) and could represent the perfect palindromic AuxRE, similar to the perfect palindromic GRE (4).

As the COOH-terminal box-motif has no apparent effect on ARF1 binding to DNA, what might be its function? We used the COOH-terminal region of ARF1 as bait in a yeast two-hybrid screen (14) and isolated two identical cDNA clones from an *Arabidopsis* cDNA expression library. The translated open reading frame encoded a protein (ARF1-Binding Protein or ARF1-BP) that contained a region with amino acid sequence similarity to boxes III and IV of ARF1 (Fig. 2, A and C). ARF1-BP showed less similarity to boxes III and IV in Aux/IAA and IAA24 proteins. Thus, boxes III and IV in ARF1 may facilitate interaction of ARF1 with ARF1-BP, and these interactions may contribute to auxin responsiveness.

Genetic approaches to dissect the auxin signal transduction pathway have resulted in the cloning of *AUX1*, *AUX1*, and *hookless1* genes (15). Identification of the relevant transcription factors should facilitate elucidation of the mechanisms involved in auxin-regulated gene expression.

5. The P3(4x) AuxRE was placed upstream of the minimal promoter in pHS-1 and pLacZ vectors (MATCH-MAKER One-Hybrid System; Clontech). These vectors were linearized and sequentially transformed into the yeast strain Y4271 (Clontech). Background LacZ activity in late logarithmic-phase cells for the engineered strain Y4271::P3(4x) was higher than for the pLacZ vector (no AuxREs) but low enough to distinguish from a positive interaction. Low plating density (10^4 cells per 150-mm plate) and 3-aminotriazole (3-AT; 45 mM) were used to suppress growth on histidine-deficient (-His) plates resulting from the low amount of P3(4x)::HIS3 reporter gene expression. An *Arabidopsis* cDNA expression library cloned into the GAL4 activation domain vector pGAD10 (Clontech) was amplified in *Escherichia coli*. Purified library DNA (500 µg) was used to transform the Y4271::P3(4x) strain. Of 1.2×10^6 transformants, 500 colonies grew on -His plates containing 3-AT, and these were screened for lacZ activity. LacZ-positive colonies (212) were selected, and library plasmids were isolated. Sizes of the cDNA inserts were determined by polymerase chain reaction (PCR) with primers that flanked the cDNA inserts. Plasmids harboring different-sized inserts were rescued by transformation into *E. coli* and retransformed into the Y4271::P3(4x) strain. Clones that restored lacZ activity were sequenced, and five clones encoding ARF1 were recovered.
6. An ARF3 cDNA (GenBank accession number U89926) was isolated from the MATCH-MAKER cDNA library by using an unannotated *Arabidopsis* sequence (GenBank accession number U78721) related to the NH₂-terminal region of ARF1.

Large Porous Particles for Pulmonary Drug Delivery

David A. Edwards,* Justin Hanes, Giovanni Caponetti, Jeffrey Hrkach, Abdelaziz Ben-Jebria, Mary Lou Eskew, Jeffrey Mintzes, Daniel Deaver, Noah Lotan, Robert Langer*

A new type of inhalation aerosol, characterized by particles of small mass density and large size, permitted the highly efficient delivery of inhaled therapeutics into the systemic circulation. Particles with mass densities less than 0.4 gram per cubic centimeter and mean diameters exceeding 5 micrometers were inspired deep into the lungs and escaped the lungs' natural clearance mechanisms until the inhaled particles delivered their therapeutic payload. Inhalation of large porous insulin particles resulted in elevated systemic levels of insulin and suppressed systemic glucose levels for 96 hours, whereas small nonporous insulin particles had this effect for only 4 hours. High systemic bioavailability of testosterone was also achieved by inhalation delivery of porous particles with a mean diameter (20 micrometers) approximately 10 times that of conventional inhaled therapeutic particles.

Inhaled aerosols are effective therapeutic carriers for the treatment of respiratory inflammation (1), cystic fibrosis (2), and other lung disorders (3); they also offer potential for non-invasive systemic delivery of peptides and pro-

teins (4). Local and systemic inhalation therapies can often benefit from a controlled release of the therapeutic agent (5), as is achievable with the use of biodegradable polymeric materials (6). Slow release from an inhaled therapeutic particle can prolong the residence of an administered drug in the airways or acini and can diminish the rate of a drug's appearance in the bloodstream (7). Also, patient compliance increases when dosage frequency is reduced (7).

The human lungs, however, have efficient means of removing deposited particles over periods ranging from minutes to hours. In the upper airways, ciliated epithelia contribute to the "mucociliary escalator" (8), by which particles are swept from the airways toward the mouth. In the deep lungs, an army of alveolar macrophages is capable of phagocytosing particles soon after their deposition (9). An effective slow-release inhalation therapy therefore requires a means of avoiding or suspend-

ing the lungs' natural clearance mechanisms until encapsulated drugs have been effectively delivered.

Until now, therapeutic dry powder aerosols have been made with particle mass densities (ρ) of $\sim 1 \pm 0.5 \text{ g/cm}^3$ and mean geometric diameters (d) of $< 5 \mu\text{m}$ to avoid excessive deposition in the dry powder inhaler (DPI) and oropharyngeal cavity (5, 10). Here, we show that very light particles ($\rho < \sim 0.4 \text{ g/cm}^3$) with $d > 5 \mu\text{m}$ can be deposited in the lungs. As a consequence of their large size and low mass density, porous particles can aerosolize from a DPI more efficiently than smaller nonporous particles, resulting in higher respirable fractions of inhaled therapeutics. Also by virtue of their size, large particles can avoid phagocytic clearance from the lungs until the particles have delivered their therapeutic dose; this attribute can be particularly useful for controlled-release inhalation therapies.

To assess the merits of large porous particles for pulmonary drug delivery, we encapsulated model therapeutics inside porous particles (Fig. 1A) composed of 50:50 poly(lactic acid-co-glycolic acid) (PLGA). Double- and single-emulsion solvent evaporation techniques (11) were used to prepare porous and nonporous PLGA particles, respectively. Porous and nonporous particles of similar aerodynamic diameter (12), loaded with ~ 15 weight % model therapeutic (testosterone), were aerosolized into a cascade impactor system (13) from a Spinhaler DPI for 30 s at an airflow rate of 28.3 liter/min. The cascade impactor provides an in vitro system for estimating the respirable fraction of a dry powder; it consists of a closed chamber within which flat plates are arranged perpendicular to the airflow, such that particles deposit stagewise in a manner reflective of their aerodynamic diameters. After deposition on the stages of the impactor, particles were collected (13) and total particle mass was assessed stagewise; the respirable fraction was determined as the percent of total particle mass exiting the DPI, recovered from the terminal, "respirable" stag-

es of the impactor. Nonporous particles ($d = 3.5 \mu\text{m}$, $\rho = 0.8 \text{ g/cm}^3$) (14) exhibited a respirable fraction of $20.5 \pm 3.5\%$, whereas $50 \pm 10\%$ of porous particles ($d = 8.5 \mu\text{m}$, $\rho = 0.1 \text{ g/cm}^3$) were respirable, even though the aerodynamic diameters (12) of the two particle types are nearly identical. The large porous particles' high efficiency can be attributed to their smaller surface-to-volume ratio. Large particles aggregate less than small particles, all other considerations being equal (15, 16); thus, while both have identical aerodynamic diameters, the large particles tend to exit the DPI more generally as single particles. The smaller particles aggregate more, leading to their deposition by gravity and inertia before reaching the "respirable" stages of the impactor.

To assess the influence of particle composition, we aerosolized a second type of porous particle (Fig. 1B), composed of poly(lactic acid-co-lysine-graft-lysine) (PLAL-Lys) (11). The PLAL-Lys particles exhibit some hygroscopicity, possibly a result of their lysine content, whereas the PLGA particles do not. Porous PLAL-Lys aerosols ($d = 8.2 \mu\text{m}$, $\rho < 0.1 \text{ g/cm}^3$) exhibited an in vitro respirable fraction ($57 \pm 1.9\%$) similar to that of the porous PLGA particles ($50 \pm 10\%$), which suggests that absolute particle mass density, rather than particle chemistry or hygroscopicity, is the prime determinant of the relatively high respirable fractions observed for the large porous particles. The values of $50 \pm 10\%$ and $57 \pm 1.9\%$ for porous particles exceed comparable respirable fractions obtained in recent aerosolization studies (15) performed with mannitol ($4 \pm 0.3\%$) and recombinant human granulocyte colony-stimulating factor (blended with mannitol) ($34 \pm 2\%$) powders using a Spinhaler DPI at a similar airflow rate (30 liter/min).

To determine whether the relatively efficient in vitro aerosolization of large porous particles translates into improved respirable fractions in vivo, we aerosolized porous and nonporous particles into the airways of rats

Fig. 2. Total particle recovery in rat lungs after bronchoalveolar lavage. Lobe numbers correspond to (1) left lung, (2) anterior, (3) median, (4) posterior, and (5) postcausal. For porous PLAL-Lys particles, $d = 8.9 \pm 4.2 \mu\text{m}$ and $\rho = 0.1 \text{ g/cm}^3$. For nonporous PLA particles, $d = 6.7 \pm 3.2 \mu\text{m}$ and $\rho = 0.84 \text{ g/cm}^3$. Means and SEs are based on $n = 4$.

(17). During forced ventilation, rats were exposed to porous or nonporous particles; bronchoalveolar lavage was used to collect particles deposited in the trachea as well as in the airways and acini (18). The nonporous particles deposited primarily in the trachea ($\sim 79\%$ of all particle mass that entered the trachea), whereas only 46% of the porous particle mass deposited in the trachea. Particles remaining in the rat lungs after bronchoalveolar lavage were obtained by careful dissection of the individual lobes of the lungs in subsequent experiments (19) (Fig. 2). The absolute number of porous particles remaining in the lungs was approximately an order of magnitude greater than the corresponding number of nonporous particles.

The role of low mass density in rendering large particles respirable can be understood in terms of the particles' mean aerodynamic diameter (12). Relatively large particles with high porosity have the same aerodynamic diameter as smaller, nonporous particles; these larger particles can enter the lungs because particle mass dictates the location of aerosol deposition in the lungs. The increased aerosolization efficiency of large, light particles lowers the probability of deposition losses before particle entry into the airways, thereby increasing the systemic bioavailability of an inhaled drug.

To test whether large particle size can increase systemic bioavailability, we encapsulated insulin into porous and nonporous polymeric particles. We designed the mass densities and mean diameters of the two particles such that they each had an aerodynamic diameter ($\sim 2 \mu\text{m}$) suitable for deep lung deposition (12); the mean diameters of the porous and nonporous particles were $> 5 \mu\text{m}$ and $< 5 \mu\text{m}$, respectively (Fig. 3, A to C). Identical masses of the porous or nonporous particles were administered to rats as an inhalation aerosol or injected subcutaneously (controls)

(20). Serum insulin concentrations were monitored as a function of time after inhalation or injection. For both porous (Fig. 3A) and nonporous (Fig. 3B) particles, blood levels of insulin reached high values within the first hour after inhalation. Only with large porous particles did blood levels of insulin remain elevated ($P < 0.05$) beyond 4 hours, with a relatively constant insulin release continuing to at least 96 hours ($0.04 < P < 0.2$). These results were confirmed by serum glucose values (Fig. 3C), which show falling glucose levels for the first 10 hours after inhalation of the porous insulin particles, followed by relatively constant low glucose levels for the remainder of the 96-hour period [for small nonporous insulin particles, initially suppressed glucose values rose after 24 hours (21)]. Similar biphasic release profiles of macromolecules from PLGA polymers have been

reported (22). For the large porous particles, insulin bioavailability relative to subcutaneous injection (23) was 87.5%, whereas the small nonporous particles yielded a relative bioavailability of 12% after inhalation. By comparison, bioavailability (relative to subcutaneous injection) of insulin administered to rats as an inhalation liquid aerosol has been reported as 37.3% using a similar endotracheal method (24). The absolute bioavailability of insulin inhaled into rat lungs in the form of a lactose-insulin powder through a DPI connected to an endotracheal tube has been reported as 6.5% (25). The longest sustained insulin release previously reported (6 hours) was achieved using liposomes intratracheally instilled into rat lungs (26).

Given the short systemic half-life of insulin (11 min) (27) and the 12- to 24-hour time scale of particle clearance from the central

and upper airways (5), the appearance of exogenous insulin in the bloodstream several days after inhalation appears to indicate that large porous particles achieve long, non-phagocytosed lifetimes in the deep lungs. To test this hypothesis, we lavaged (18) the lungs of rats immediately after inhalation of the porous and nonporous insulin particles as well as 48 hours after inhalation. For nonporous particles, $30 \pm 3\%$ of phagocytic cells contained particles immediately after inhalation, and $39 \pm 5\%$ contained particles 48 hours after inhalation. By contrast, only $8 \pm 2\%$ of phagocytic cells contained large porous particles immediately after inhalation, and $12.5 \pm 3.5\%$ contained particles 48 hours after inhalation. For small nonporous particles, $17.5 \pm 1.5\%$ of the phagocytic cell population contained three or more particles 48 hours after inhalation, compared with $4 \pm 1\%$ for large nonporous particles. Inflammatory response was also elevated with small nonporous particles; neutrophils represented $34 \pm 12\%$ of the phagocytic cell population 48 hours after inhalation of the small nonporous particles, compared with $8.5 \pm 3.5\%$ for large porous particles (alveolar macrophages represented 100% of cells measured immediately after inhalation). These results are consistent with those of *in vitro* experiments showing that phagocytosis of particles diminishes precipitously as particle diameter increases beyond $3 \mu\text{m}$ (28).

To further determine whether increased bioavailability correlates with increasing size of porous particles, we encapsulated a second model drug, testosterone, in porous particles of two different mean geometric diameters (10.1 and $20.4 \mu\text{m}$). An identical mass of powder was administered to rats as an inhalation aerosol or as a subcutaneous injection (controls). Serum testosterone concentrations were monitored as a function of time after inhalation or injection (Fig. 3, D and E). Blood levels of testosterone remained well above background levels ($P < 0.05$) for 12 to 24 hours, even though the systemic half-life of testosterone is 10 to 20 min (27). Testosterone bioavailability relative to subcutaneous injection was 177% for the $20.4\text{-}\mu\text{m}$ -diameter particles (Fig. 3D) and 53% for the $10.1\text{-}\mu\text{m}$ -diameter particles (Fig. 3E). The increase in testosterone bioavailability with increasing size of porous particles is especially notable given that the mean diameter of the $20.4\text{-}\mu\text{m}$ particles is ~ 10 times that of nonporous conventional therapeutic particles (5, 10). The relatively short time scale of testosterone release observed for both the inhalation and subcutaneous controls is near the *in vitro* time scale of release (several hours) reported elsewhere for 50:50 PLGA microparticles of similar size encapsulating a therapeutic substance (bupivacaine) of similar molecular weight and lipophilicity (29).

Fig. 3. Systemic concentrations in rats after administration of porous and nonporous therapeutic particles. (A) Serum insulin concentration after inhalation and subcutaneous injection of 9 mg of large porous insulin particles. No insulin particles were administered to nontreated controls. Porous particles contained insulin (20.0 weight %) and 50:50 PLGA (80.0 weight %) (11). Their mean d and d_{50} values were $6.8 \mu\text{m}$ and $2.15 \mu\text{m}$, respectively. Means and SEs are based on $n = 3$. (B) Serum insulin concentration after inhalation

and subcutaneous injection of 9 mg of small nonporous insulin particles. No insulin particles were administered to nontreated controls. Nonporous particles contained insulin (10.0 weight %) and 50:50 PLGA (90.0 weight %) (11). Their mean d and d_{50} values were $4.4 \mu\text{m}$ and $2.15 \mu\text{m}$, respectively. Means and SEs are based on $n = 3$. (C) Serum glucose concentration after inhalation of 9 mg of large porous insulin particles or 9 mg of small nonporous insulin particles. No insulin particles were administered to nontreated controls. Means and SEs are based on $n = 3$. (D) Serum testosterone concentration after administration of 6 mg of porous testosterone particles ($d = 20.4 \mu\text{m}$) as an inhalation powder and as a subcutaneous control. Particles contained testosterone (15 weight %), 50:50 PLGA (78.5 weight %), and PLAL-Lys (8.5 weight %). For the dry powder, $\rho = 0.1 \text{ g/cm}^3$. (E) Same as (D) but with smaller porous testosterone particles ($d = 10.1 \mu\text{m}$).

Porous particles comprising therapeutics and pharmaceutical excipients can easily be formed by spray-drying (30), rapid expansion of supercritical fluids (31), and other particle formation technologies. Hence, they can immediately address a variety of needs as therapeutic carriers for inhalation therapies. Their potential for high aerosolization efficiency, long-term drug release, and increased systemic bioavailability makes large porous particles especially attractive for systemic inhalation therapies.

- PLGA particles were made using the double- and single-emulsification solvent evaporation procedures. In the double-emulsification procedure, 300 μ l of an aqueous solution was emulsified on ice into 4.0 ml of 50:50 PLGA polymer solution in methylene chloride (200 mg of polymer) by probe sonication. The first emulsion was poured into 100 ml of 1% aqueous polyvinyl alcohol (PVA) solution (average molecular weight 25 kD, 88% hydrolyzed) and homogenized (Silverson Machines, London, England) at 5000 rpm to form the double emulsion. The microspheres were continuously stirred for 3 hours to allow hardening, collected by centrifugation, washed several times with double-distilled water, and freeze-dried into a freely flowing powder. Particles (PLGA or blends of PLGA and PLAL-LYS) containing testosterone were made by dissolving the testosterone in the polymer solution. For the insulin particles, an aqueous solution of human insulin was emulsified with PLGA in the first emulsification. The amounts of water and insulin were decreased to diminish particle porosity, whereas insulin microsphere aerosolization efficiency was enhanced by the addition of L- α -phosphatidylcholine dipalmitoyl to the polymer solution [J. Hanes, thesis, Massachusetts Institute of Technology (1996)]. In the single-emulsification method, 200 mg of the copolymer 50:50 PLGA was dissolved in 2.8 ml of methylene chloride. The polymer solution was homogenized at 7500 rpm in 100 ml of 1% (w/v) aqueous PVA solution. The resulting dispersion was stirred using a magnetic stirrer for 3 hours until the methylene chloride was completely evaporated and the particles hardened. The particles were then isolated by centrifugation. The precipitate was washed three times with distilled water. Finally, the particles were freeze-dried (Labconco freeze dryer 8) for at least 48 hours. Particle sizing was performed using a Coulter Multisizer II (Coulter Electronics, Luton, England). PLGA particles prepared by the single-emulsification method are naturally less porous than those made by double emulsification. For example, PLGA microspheres with bulk mass densities as low as 0.05 g/cm³ have been prepared by the double-emulsification technique [R. Jeyaraj, B. C. Thano, R. C. Matha, P. P. DeLuca, *J. Controlled Release* 38, 235 (1996)], although these microspheres, at 35 to 140 μ m, were inappropriately large for deep-lung inhalation. PLAL-LYS particles were also made using the single-emulsification technique [J. S. Hirsch, J. O. A. Lotan, R. Langer, *Macromolecules* 28, 4738 (1995)]; these particles, apparently because of the cationic charge of the graft copolymer, are highly porous even when prepared by the single-emulsification method.
- The aerodynamic diameter d_{ae} is related to the actual sphere diameter d by the formula

$$d_{ae} = d \sqrt{\rho} \quad (1)$$
 (5). Maximal deposition of monodisperse aerosol particles in the alveolar region of the human lung (~60% of the inhaled particles) occurs for $d_{ae} = 3-5 \mu$ m (32). Inhaled particles with $d_{ae} > 3 \mu$ m tend to deposit in the upper airways by gravity and inertia, whereas particles with $d_{ae} < 3 \mu$ m tend to be exhaled. On the basis of Eq. 1, the actual diameter d (in micrometers) of porous particles that will exhibit maximum deep-lung deposition because of their small ρ is

$$d = 3/\sqrt{\rho} \quad (2)$$
 (where $\rho < 1$). Hence, for such particles d is always greater than 3 μ m. For example, porous particles with $d = 8.5 \mu$ m and $\rho = 0.1$ g/cm³ have approximately the same aerodynamic diameter (~2.7 μ m) as nonporous particles with $d = 3.5 \mu$ m and $\rho = 0.8$ g/cm³.
- We placed 20 mg of porous or nonporous microparticles, with encapsulated rhodamine as a fluorescent marker, in No. 1 hard gelatin capsules (Eli Lilly), loaded the capsules into a Spinhaler DPI (Pneum, Bedford, MA), and activated the DPI. Particles were aerosolized into a Mark I Andersen Impactor (Andersen Samplers, Atlanta, GA) from the Spinhaler device for 30 s at a flow rate of 28.3 l/min. (Each plate of the impactor was previously coated with Tween 80 by immersing the plates in an acetone solution (5% w/v) and then evaporating the acetone in an oven at 60°C for 5 min.) After aerosolization and deposition, particles were collected from each stage of the impactor system and completely degraded in NaOH solution (0.2 N). After incubation at 37°C for 12 hours, the fluorescence of each solution was measured (wavelengths of 554 nm excitation, 574 nm emission).
- Particle mass density was determined either by non-mercury porosimetry or tap density measurements (Micromeritics, Norcross, GA). The mass density of nonporous particles ranged from ~0.4 to 1.0 g/cm³. The lower mass density limit (0.4 g/cm³) is near that recently reported for spray-dried pharmaceutical powders (15), whereas the upper limit (1.0 g/cm³) is similar to the mass density of liquid pharmaceutical aerosols [A. Adjei et al., *Int. J. Pharm.* 107, 57 (1994)] and other dry-powder aerosols [M. T. Vidgren, P. A. Vidgren, T. P. Paronen, *ibid.* 35, 139 (1987)]. The mass density of porous particles was typically near or equal to 0.1 g/cm³. Mass density variation from particle to particle within powders did not appear to introduce a substantial source of uncertainty. For example, using an API aerosolizer, we measured the mean time-of-flight of the porous and nonporous particles described in the legend of Fig. 2. This gave a mean d_{ae} of $1.57 \pm 2.41 \mu$ m for the porous particles and $5.82 \pm 1.88 \mu$ m for the nonporous particles. Using Eq. 1 in (12), this indirectly yields a mass density ratio (porous to nonporous) of 0.1 ± 0.3 . Given that the measured ratio of mass densities is 0.11 (Fig. 2), mass density variation within the two powders appears to be small (<10%).

- W. I. Li et al., *ibid.*, p. 1269.
- Male Sprague-Dawley rats (150 to 200 g) were anesthetized using ketamine (80 mg/kg)-xylazine (10 mg/kg). Anesthetized rats were placed ventral side up on a surgical table provided with a temperature-controlled pad to maintain physiological temperature. Rats were cannulated above the carina with an endotracheal tube connected to a Harvard ventilator and were force-ventilated for 20 min at 300 ml/min. Fifty micrograms of porous (PLAL-LYS) or nonporous (PLA) microparticles were introduced into the endotracheal tube. After the period of forced ventilation, rats were killed and the lungs and trachea were separately washed using bronchoalveolar lavage (7). The lavage fluid was centrifuged (400g), and the pellets were collected and resuspended in 2 ml of phenol red-free Hank's balanced salt solution (HBSS) (Gibco) without Ca²⁺ and Mg²⁺. A 100- μ l sample was removed for particle counting using a hemacytometer. The remaining solution was mixed with 10 ml of 0.4 N NaOH. After incubation at 37°C for 12 hours, the fluorescence of each solution was measured (wavelengths of 554 nm excitation, 574 nm emission).
- Lungs were lavaged immediately (5 to 10 min) after inhalation. A tracheal cannula was inserted and tied into place, and the airways were washed with 10-ml aliquots of HBSS. The lavage procedure was repeated until a total volume of 30 ml was collected. In the phagocytic cell experiments, lavage fluid was centrifuged and the cell pellets were resuspended in HBSS for counting, differentiation of cell types, and measurement of phagocytosis. Engagement of particles by phagocytic cells was determined by counting microscopically the number of particles incorporated per cell in wet mounts and in fixed and stained cytocentrifuge preparations. Reported numbers are based on the wet-mount experiments; similar numbers were obtained using the stained cytocentrifuge preparations.
- The lobes were placed in separate petri dishes containing 5 ml of HBSS. Each lobe was teased through a 60-mesh screen to dissociate the tissue and was then filtered through cotton gauze to remove tissue debris and connective tissue. The petri dish and gauze were washed with an additional 15 ml of HBSS to maximize microparticle collection. Each tissue preparation was centrifuged and resuspended in 2 ml of HBSS, and the particles were counted in a hemacytometer.
- Rats were anesthetized and cannulated as described (17) and were force-ventilated for 10 to 20 min at 300 ml/min. Rats received two types of aerosols through the endotracheal tube. After the period of forced ventilation, necks were sutured and rats were revived within 1 to 2 hours. Blood samples (300 μ l) were periodically withdrawn from the tail vein over a period of 2 to 6 days. These samples were mixed with assay buffer, centrifuged, and the supernatant examined for the presence of (endogenous and exogenous) insulin or testosterone using radioimmunoassays (ICN Pharmaceuticals, Costa Mesa, CA). Glucose was measured using a colorimetric assay (Sigma). Control studies involved subcutaneous injection of the same amount of powder as was inhaled. The particles were injected into the scruff of the neck.

(Crystal data (II) for some androstanes). By JEAN M. OHRT, BARBARA A. HANER and DORITA A. NORTON, *Biophysics Department, Roswell Park Memorial Institute, Buffalo, New York 14203, U.S.A.*

(Received 2 February 1965)

Norton, Lu & Campbell (1962) reported the single-crystal data for a series of androstanes. This paper reports the same data for a second set of androstanes (Table I) using the

same techniques described in the earlier paper. No further work on these compounds is contemplated.

An X-ray investigation of the stereochemistry of $Zn(NCS)_2(C_6H_5NH_2)_2$. By T. M. SHEPHERD and IDA WOODWARD, *Chemistry Department, Queen's University of Belfast, Belfast, Northern Ireland.*

(Received 22 June 1964)

The stereochemistry of the complex $Zn^{II}(NCS)_2(C_6H_5NH_2)_2$ is of interest in connection with studies in these laboratories on the factors governing the configuration of metal complexes. Nelson & Shepherd (unpublished work) have established, from magnetic and spectral data, that the corresponding $Cu(II)$ and $Ni(II)$ complexes have octahedral (or tetragonal) structures with bridging NCS groups. X-ray powder patterns show that these and the corresponding $Cd(II)$ complex are isomorphous, but that $Zn(NCS)_2(C_6H_5NH_2)_2$ has a different crystal structure. An attempt to determine this structure sufficiently to establish the coordination number of the zinc atom is described here.

Single crystals obtained by recrystallization from ethanol were used. These were needle-shaped, approx 1.5 mm long,

and 0.3 mm in cross section. The needle axis being taken as the c axis, rotation photographs with $Cu K\alpha$ radiation about the [001] and [110] axes and Laue photographs showed the unit cell to be orthorhombic with the cell dimensions:

$$\begin{aligned}a &= 14.56 \pm 0.05 \text{ Å} \\b &= 9.10 \pm 0.05 \\c &= 12.7 \pm 0.1\end{aligned}$$

The values for a and b were derived from the observed spacings of 39 hkl reflexions, and their uncertainties are an estimate based on the standard deviations of the observed and calculated values. c was obtained from layer line measurements of a rotation photograph.

Acta Cryst. (1970). B26, 1184

Crystallographic data for testosterone hydrate and anhydrate. By A. L. THAKKAR, N. D. JONES, H. A. ROSE, L. G. TDSMEYER and N. A. HALL,* *Lilly Research Laboratories, Eli Lilly and Company, Indianapolis, Indiana 46206, U.S.A.*

(Received 15 January 1970)

Testosterone hydrate crystallizes in the space group $P2_12_12_1$ with four molecules in a unit cell having the dimensions $a=13.63$, $b=15.95$ and $c=7.94$ Å. Anhydrous testosterone crystallizes in the space group $P2_1$ with four molecules in the unit cell. The proper cell dimensions are $a=14.45$, $b=11.09$, $c=10.88$ Å and $\beta=110.5^\circ$.

In a previous study on the solution behavior of testosterone in aqueous media, conversion of the anhydrate form to a hydrate was reported (Thakkar & Hall, 1969). Since testosterone is a natural hormone and exists in an aqueous environment, characterization of this form is important. We wish to report here the crystallographic parameters of the hydrate.

Small single-crystals were grown by a continuous fall method from saturated aqueous solution cooled from 33.0 to 29.5°C at 0.1°C per hour. Elemental analysis, Karl Fischer titration and thermogravimetric analysis showed this crystalline form to be the monohydrate.

From Weissenberg and precession photographs taken with Cu K α radiation the space group has been found to be $P2_12_12_1$ (systematic absences: $h00$, $0k0$, and $00l$ for h , k or l odd); there are four molecules in a unit-cell having the dimensions $a=13.63$, $b=15.95$ and $c=7.94$ Å. The density measured by displacement is 1.181 g.cm $^{-3}$, which agrees well with the calculated density for $C_{19}H_{28}O_2 \cdot H_2O$ of 1.179 g.cm $^{-3}$.

* Present address: College of Pharmacy, University of Washington, Seattle, Washington 98105.

For comparison we have measured the crystal parameters for anhydrous testosterone and have obtained values which differ from those reported by Bernal & Crowfoot (1936). The space group is $P2_1$ with four molecules in a unit-cell having the dimensions $a=14.73$, $b=11.09$, $c=10.88$ Å and $\beta=113.3^\circ$, which agree fairly well with the values given by Ohrt, Haner & Norton (1965). There is, however, an alternative cell with β closer to 90° . The dimensions for this proper cell are $a=14.45$, $b=11.09$, $c=10.88$ Å and $\beta=110.5^\circ$. These cells give a calculated density of 1.173 g.cm $^{-3}$, which is identical with the experimentally measured value given by Bernal & Crowfoot.

The indexed powder data for these two forms of testosterone will be submitted for inclusion in the *ASTM Powder Diffraction File*.

Crystal data of $BaSrFe_4O_{10}$. By S. MERIANI and G. SLOCCARI, *Istituto di Chimica Applicata dell'Università di Trieste, via Valerio 2, Trieste, Italy.*

(Received 20 January 1970)

The dimensions of the orthorhombic unit cell of $BaSrFe_4O_{10}$, which contains two formula units, are $a=5.516$, $b=8.265$, $c=9.188$ Å. The space group is $Pnma$.

A previous report on the phase equilibrium diagram, BaO - SrO - Fe_2O_3 , shows that a new stable compound, having the composition $BaSrFe_4O_{10}$, may occur as a single phase above $1100 \pm 10^\circ\text{C}$ (Batti, 1962). It undergoes thermal transformation at about 1200°C and melts incongruently at $1240 \pm 10^\circ\text{C}$. A further investigation by Barbariol & Batti (1968) established that this new phase forms a solid solution with the binary compound $BaFe_2O_6$, which is reported to be orthorhombic (Okazaki, Mori & Mitsuoka,

1963; DoDinh & Bertaut, 1965). They display complete solubility above 1200°C whereas at lower temperatures a solid-solution gap of increasing width was reported.

Single crystals of $BaSrFe_4O_{10}$ were grown, by solid-state reaction, from a pressed pellet mixture of $1 BaCO_3$: $1 SrCO_3$: $2 Fe_2O_3$, which was heated on a platinum strip in a resistance furnace to about 950°C . The sintered pellet was reground and refired to assure complete reaction. The microcrystalline specimen was brought to 1200°C and left in the furnace

Acta Cryst. (1964). 17, 1611

Crystal data (II) for some estrone-related compounds.* By JEAN M. OHRT, BARBARA A. HANKE, and DORITA A. NORTON, Department of Biophysics, Roswell Park Memorial Institute, Buffalo, New York, U.S.A.

(Received 1 May 1964)

The lattice constants of eleven estrone-related compounds (Table 1) were determined on a General Electric XRD 5 X-ray diffraction unit equipped with a goniostat using $\text{Cu K}\alpha$ radiation. Space groups were established on the basis of systematic absences and optical activity.

All crystals were grown from solution. Flotation density measurements were used to calculate the number of molecules per unit cell. The high discrepancy between the measured (D_m) and calculated (D_c) densities of compound (3) is due to the crystallization of one molecule of ethanol per molecule of steroid. The density calculated taking the solvent of crystallization molecules into

consideration is 1.151 g.cm^{-3} which agrees with the measured density. All of the other measured and calculated densities also agree within the experimental error (4.0%).

Compounds (1) and (2) each crystallized in two forms. Both of the (a) forms had similar but non-isomorphous unit cells. Compounds (2) and (3) are isomers but do not form isomorphous crystals.

* This investigation was supported in part by P.H.S. grant CY-06183 from the National Cancer Institute, Public Health Service.

CRYSTALLOGRAPHICA

DL-N-1-BUTYL-2(4-HYDROXY-3-HYDROXYMETHYLPHENYL)-2-HYDROXYETHYLAMINE, (SALBUTAMOL, Ah.3365), $C_{13}H_{21}NO_3$

by J.P. Beale* and C.T. Grainger
Crystallography Department, The University of New South Wales, Box 1, P.O.
Kensington, N.S.W. 2033, Australia

Introduction. The crystal structure of Salbutamol has been determined by X-ray diffraction. Salbutamol is one compound of a new series of β -adrenergic stimulants which have been found to have considerably greater action on bronchial smooth muscle than on other smooth muscle affected by β -stimulants, and is currently being used in many countries for the treatment and management of asthma (Hartley, Jack, Lunts and Ritchie, 1968; Brittain, Farmer, Jack, Martin and Simpson, 1968).

Crystal Data. Rectangular crystals were obtained by recrystallization from water. The space group as determined from systematic spectral absences is $Pbca$; the unit cell dimensions are: $a = 21.654(10)$, $b = 8.798(4)$, $c = 14.565(7)$ Å; $Z = 8$; $\rho_{obs} = 1.15 \text{ g cm}^{-3}$, $\rho_{calc} = 1.15 \text{ g cm}^{-3}$.

Data Collection, Structure Elucidation and Refinement. A total of 2644 independent reflections were measured on a Siemens automatic single crystal diffractometer using $\text{CuK}\alpha$ radiation and nickel attenuators (Craig, 1971). The structure was solved using direct phasing procedures incorporating programmes NORM, PHREL and GSAM written by Grainger. Reflections having $|E_{obs}| \geq 1.60$ (272 in number) were selected and used in the phase analysis and calculation of an E map from which the positions of all non-hydrogen atoms were obtained. Eventually all atoms (including hydrogens) were located and the structure refined by full matrix least squares procedures to an overall discrepancy (R) factor of 0.048. It is worth noting that comparison between the fully refined phases of the initial 272 selected reflections and those used to phase the E map revealed that only one phase was incorrectly assigned in the first instance.

Fig.2. A packing diagram showing the unit cell contents of Salbutamol.

intramolec-

Comments. Salbutamol exhibits the same cis orientation of amino and hydroxyl groups as observed with Th1165 (Seale, 1972). The N...O distance (2.826(2) Å) is in fact a little larger than the corresponding distance (2.766(3) Å) in Th1165. The benzene ring is inclined at 74.5(2)° to the

plane of the C(7)-C(8)-N-C(9) atoms, whilst in the Th1165 molecule this angle is $66.9(3)^\circ$. The tertiary butyl group is on the opposite side of the Salbutamol molecule to the amino and hydroxyl groups. The Th1165 molecule has the substituent groups on the nitrogen atom on the same side of the molecule as the amino and hydroxyl groups and therefore in closer proximity to the receptor site.

Acknowledgments. The authors are indebted to the Asthma Foundation of New South Wales for the award of a post-doctoral research Fellowship to one of us (JPB). We are also grateful to Associate Professor M.C. Stephenson for his continued interest and help, to Professor W.F. Glover and Dr. S. McLean, School of Physiology, The University of New South Wales for their assistance. We would also like to thank Professor M.M. Woolfson, Dr. P. Main (York University, England) and Dr. G. Germain (Louvain University, Belgium) for supplying us with LSAM. Finally, we would like to express our thanks to Glaxo-Allenburys (Aust.) Pty. Limited for samples of Salbutamol.
